Antihypertensives Market

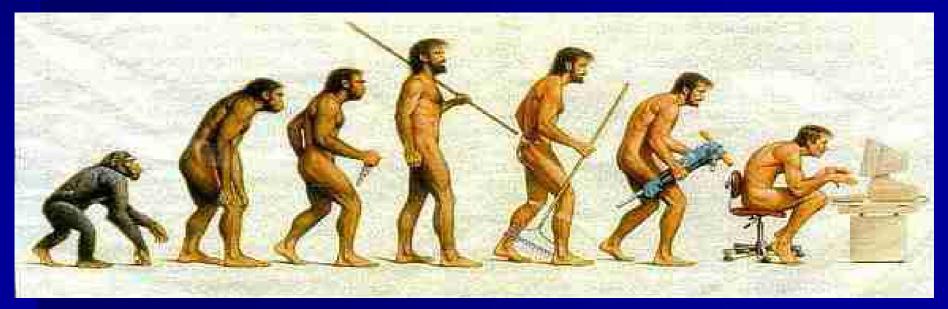

- Market Share in 2004 -

Hypertension Market

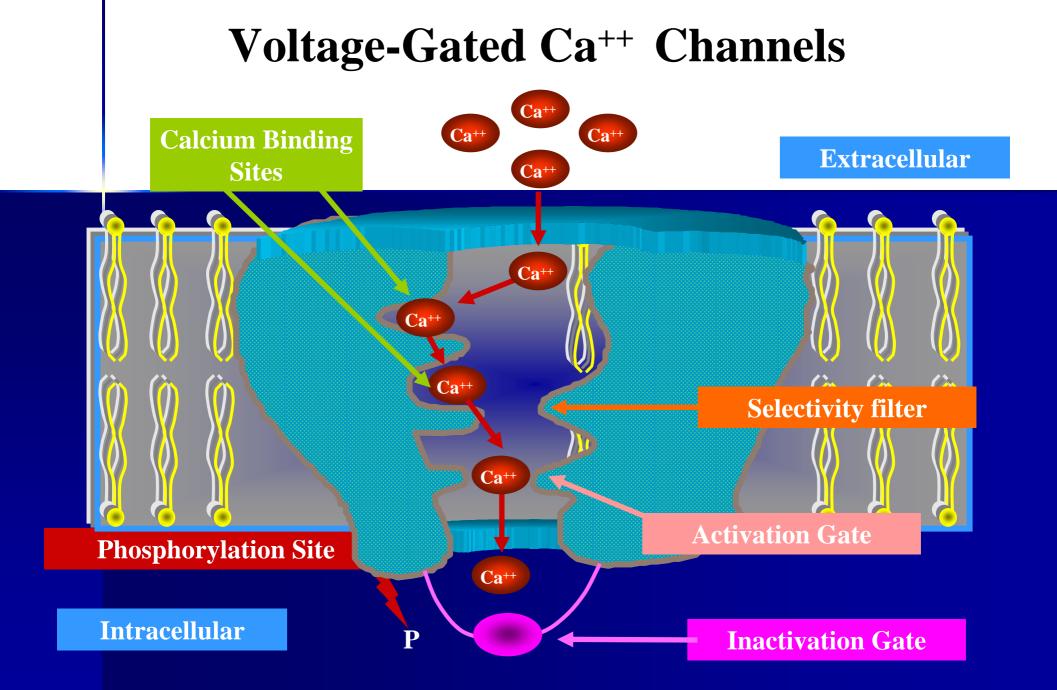

History of Calcium Channel Antagonists

- First introduced for clinical use in late 1970's
- First generation prototypical CCAs problematic with hemodynamic fluctuations
- Evolution to longer acting agents and third generation formulations

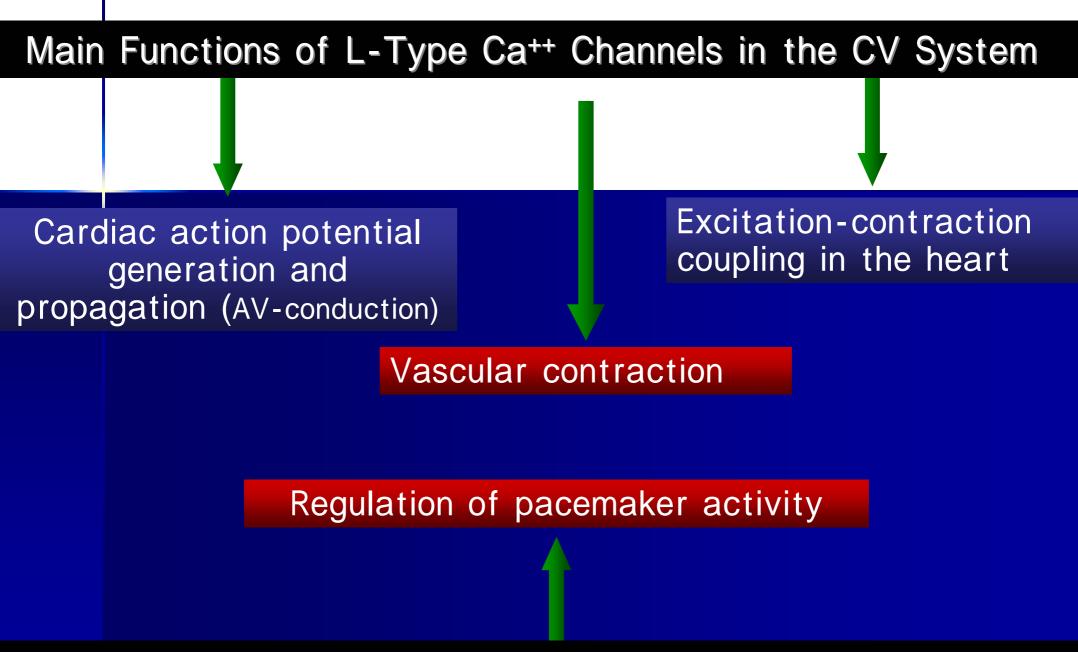

Current Recommended Uses of CCAs

- Hypertensive Therapy
- Symptomatic relief of stable angina
- "Stabilized" UA/NSTEMI
- Symptomatic relief of diastolic heart failure
- Rate control of persistent afib

| | Characteristics of Ca++ Channel Carried Currents | | | | | | | |
|---|--|--|--|--|--|--|--|--|
| L-Type | L-type currents require strong depolarization (high activation threshold), are long lasting (slow inactivation rate) and are blocked by organic calcium antagonists of dihydropyridine, phenylalkylamines and benzothiazepine chemical classes. They are the main currents recorded in muscle and | | | | | | | |
| | endocrine cells initiating contraction and secretion. | | | | | | | |
| T-Type | T-type currents are activated at weak depolarization potentials, are transient (fast inactivation) and resist to L-type and N- and P/Q-type blockers. They are involved in the shaping of the action potentials and controlling patterns of repetitive firing in a wide variety of cell types. | | | | | | | |
| N-Type | These currents also require strong depolarization stimuli for activation, but | | | | | | | |
| P-Type | are resistant to L-type blockers. They are blocked by specific polypeptide toxins isolated from cone snail and funnel web spider venoms. These currents | | | | | | | |
| Q-Type | Are found primarily in neurons where they initiate neurotransmission at the most fast synapses and contribute to Ca++ transient in cell bodies and | | | | | | | |
| R-Type | dendrites. | | | | | | | |
| L-long lasting: N-noither L. nor T. ourrente, neuronal: D-Durkinia fibere: 0-2: D-remaining, taxin registant: | | | | | | | | |

L=long lasting; N=neither L nor T currents, neuronal; P=Purkinje fibers; Q=?; R=remaining, toxin resistant; T=transiently activated.

Main Functions of T-type Ca⁺⁺ Channels in the CV system

Ca⁺⁺ Entry into the Cardiac Myocyte Induces Ca⁺⁺ Release the Sarcoplasmic Reticulum Necessary for Contraction

interaction Contraction Contraction Ca⁺⁺-induced Ca⁺⁺ release

L-type cardiac Ca⁺⁺ channels open at a level of depolarization of ~-60 mV. The entry of small amount of Ca⁺⁺ triggers Ca⁺⁺ release from SR. Thus, blockade of this channel produces negative inotropic effects.

Classes of CCB

| Chemical Group | Tissue Selectivity | 1 st Generation | 2 nd Generation | 3 rd Generation |
|-------------------|------------------------------|-------------------------------|---|----------------------------|
| Dihydropyridines | Vascular > Myocardium | Nifedipine Nicardipine | Nifedipine SR/GITS Nicardipine SR Felodipine Isradipine Nimodipine Nisoldipine Nitrendipine | Amlodipine Lacidipine |
| Benzothiazepines | Vascular = Myocardium | Diltiazem | Diltiazem SR | |
| Phenylalkylamines | Vascular < Myocardiu m | Verapamil | Verapamil SR Gallopamil | |

Cardiovascular Effects of CCB

Intended:

Vascular smooth muscle cell relaxation

Unintended:

Reflex activation of sympathetic system

- Negative inotropic effects
- Negative chronotropic effects
- Reflex activation of renin-angiotensinaldosterone system

Calcium channel blocker in Hypertension

Clinical Trials With 1st Generation CCAs

Short acting nifedipine

Nifedipine may paradoxically exacerbate the frequency of angina pectoris!!! Am Heart J 1983;106(4 pt1):644-52

> Short acting nifedipine (when given in doses > 60 mg/day) increases mortality in patients with CAD!-Circ 1995;92(5)1326-31

Diltiazem treatment associated with 63% increase in rate of MI in hypertensive patients!!! J Am Geriatr Soc 1995;274(8):620-5

Diltiazem increases risk of decompensated CHF and death in pts With post-MI LV dysfunction!!! Circ 1991;83(1):52-60

What Happened?

- Rapid onset and short duration of short-acting formulations lead to neurohormonal activation, which can be detrimental in CAD and CHF
- Because arterioles are more affected by CCA than larger epicardial arteries, "coronary steal" (to non-ischemic myocardium) via collaterals may worsen angina
- Other RCTs demonstrated that verapamil had no adverse cardiac effects, and even mortality reduction in some cases
 Verapamil is metabolized to long-acting norverapamil

2nd and 3rd Generation CCAs

- Meta-analysis of placebo controlled trials with longer-acting CCA suggest mortality *benefit* in treated patients (HTN, post-MI, CHF, CAD)¹
- RCTs with amlodipine² and felodipine³ in pts with LV dysfunction revealed equivalent (if not improved) mortality rates

Amlodipine Protects Against TNF-α-Induced Endothelial Cell Apoptosis

Amlodipine: Additional Mechanisms Under Investigation May Impact on Atherosclerosis

- Membrane-stabilizing effects
- Inhibition of smooth muscle cell migration/proliferation
- Increased nitric oxide production

Mason et al. J Mol Cell Cardiol. 1999;31:275-281. Tulenko et al. J Cardiovasc Pharmacol. 1995;26(suppl A):S11-S17. Zhang and Hintze. Circulation. 1998;97:576-580.

CCB and Atherosclerosis

CCB may have some antioxidant properties

- Small animal studies suggest that some CCBs:
 - Reduce influx of LDL into arterial wall
 - Suppress progression of atherosclerosis in aorta
 - Decrease thromboxane A2 production
- Human studies limited, less compelling
 - Some evidence suggests decrease in new plaque formation
 - Enhanced effect when given with pravastatin?
 - Stronger evidence for carotid plaque regression

ACTION: Conclusions

In pts with SAP on adequate medical therapy, nifedipine GITS:

- Lowered BP
- Raised HR
- Decreased incidence of:
 - New overt heart failure
 - Coronary angiography
 - Coronary artery bypass surgery
- Did NOT effect:
 - Cardiovascular or all-cause mortality
 - Incidence of myocardial infarction

CAD trials

- INTACT (International Nifedipine Trial on AtherosClerotic Therapy)
 - Fewer new lesions with CCBs
- MHINT (Montreal Heart Institute Nicardipine Trial)
 Less progression of minimal lesions with CCBs
- CAPARES (The Coronary AngioPlasty Amlodipine REstenosis Study)
 - Reduce need for PTCA & combined endpoint of major adverse clinical events
- PREVENT (The Prospective Randomized Evaluation of the Vascular Effects of Norvasc Trial)

Effect of Amlodipine on the Progression of Atherosclerosis and the Occurrence of Clinical Events (PREVENT)

- Goal: to determine the effects of amlodipine on atheroslcerotic progression and cardiovascular clinical events
- Patients: 825 pts with angiographic CAD
- Design:
 - Prospective, multicenter, randomized, placebo-controlled, double-masked clinical trial
 - Treatment with amlodipine vs placebo
 - 3 yr follow-up
- Outcomes measured:
 - Angiographically evaluated (non-intervened) coronary atherosclerosis
 - Carotid artery atherosclerosis (ultrasound)
 - All-cause mortality, cardiovascular events

PREVENT: Clinical **Events/Procedures**

Effect of Antihypertensive Agents on Cardiovascular Events in Patients With Coronary Disease and Normal Blood Pressure (CAMELOT)

- Goal: compare the effects of amlodipine or enalapril vs placebo in pts with CAD
- Patients: 1991 pts with angiographically documented CAD and diastolic BP <100 mmHg</p>
- Design: Multicenter, double-blind, randomized, placebocontrolled trial
- Outcomes measured:
 - Incidence of cardiovascular events (cv death, nonfatal MI, cardiac arrest, coronary revascularization, hospitalization for angina/CHF, CVA/TIA, PVD)
 - Subgroup analysis with IVUS to determine antiatherosclerotic effects

IVUS Progression: Percent Atheroma Volume

Patients with BP mean (n=136)

CAMELOT: Conclusions

In normotensive pts with CAD, additional amlodipine therapy:

Further decreases

- Overall adverse cardiovascular events
- Rates of coronary revascularization
- Hospitalization for angina
- Revascularization after MI
- Rate of coronary atherosclerotic progression
- -
- Did not effect rates of:
 - Cardiovascular and all-cause mortality
 - Nonfatal MI or CVA
 - Hospitalization for CHF

Conclusions

Not all CCBs are created equally

- 1st generation, short-acting formulations may be detrimental in CAD, CHF
- 2nd & 3rd generation, long-acting formulations are generally safer

CCBs have a well-established role in treating HTN and angina

Conclusions

In stable pts, CCBs:

- May have additional benefits of carotid plaque regression and CVA reduction
- Have equivalent mortality rates compared to diuretic, beta-blocker and ARB therapy
- Have equivalent (or more favorable) rates of MI
- Decrease anginal symptoms and need for invasive procedures
- (DHPs) do not increase risk of CHF
