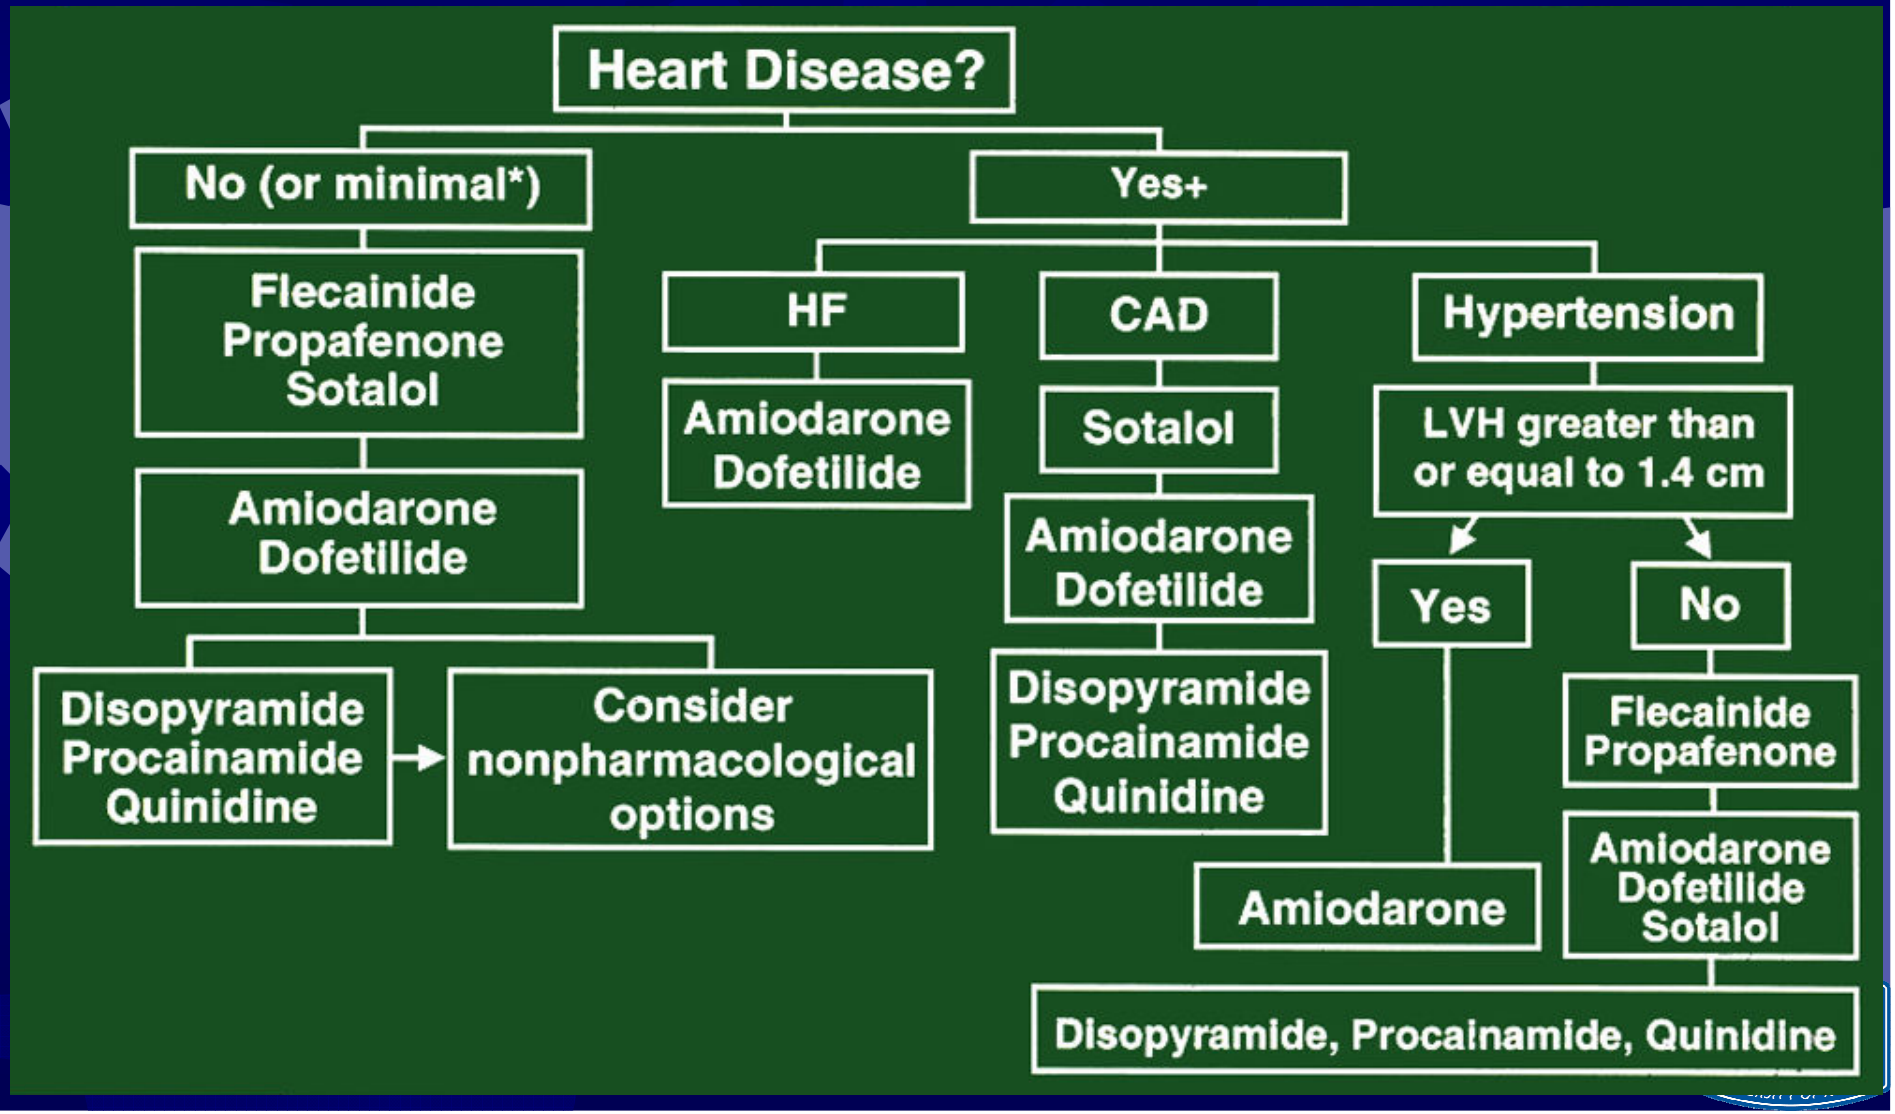
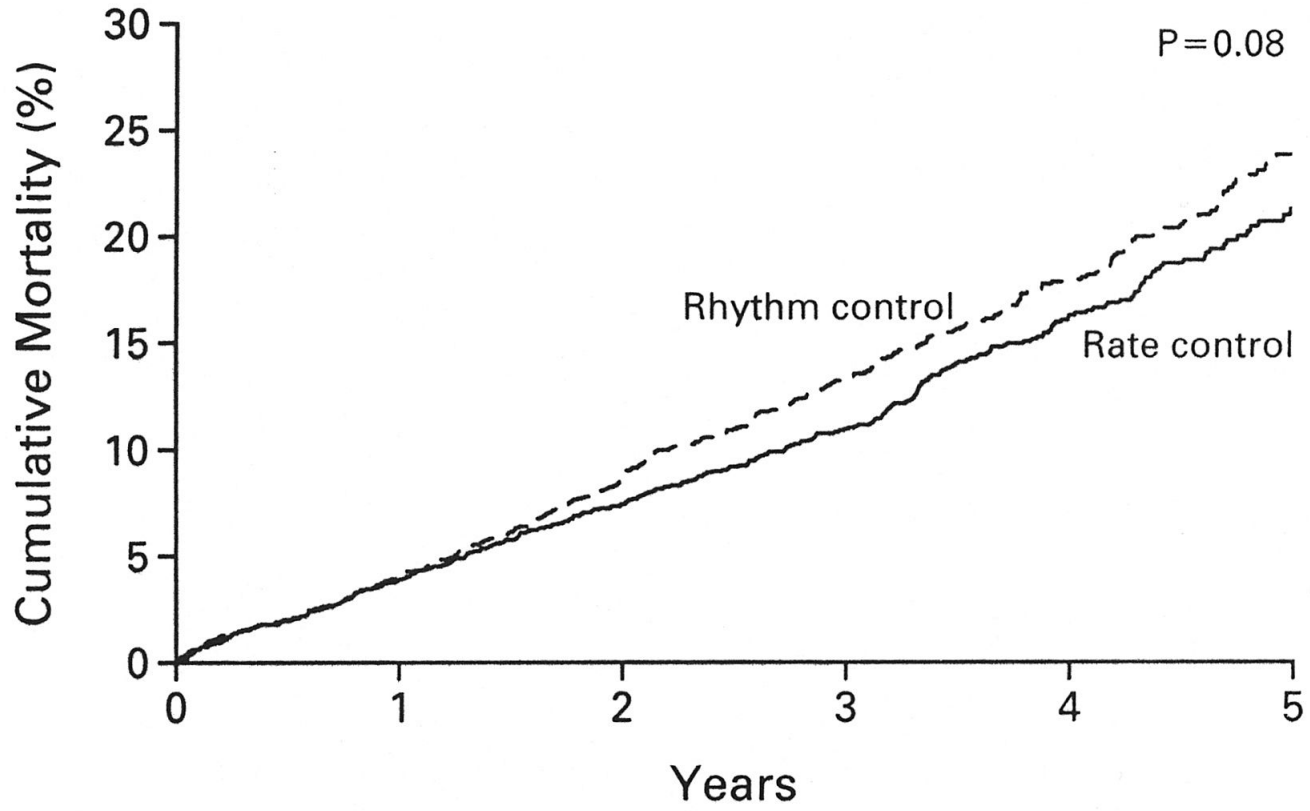
Antiarrhythmic Drug Therapy to maintain Sinus Rhythm in Patients with Recurrent Paroxysmal or Persistent AF

ACC/AHA/ESC Guidelines, 2001



Rate Versus Rhythm Control in Patients with A. Fib (AFFIRM)



No. of Deaths		number (percent)				
Rhythm control	0	80 (4)	175 (9)	257 (13)	314 (18)	352 (24)
Rate control	0	78 (4)	148 (7)	210 (11)	275 (16)	306 (21)

From: AFFIRM investigators NEJM 2002; 347:1825

Rhythm versus Rate Control Trials in Patients with Atrial Fibrillation: General Characteristics

	N	Mean Age (yr)	Follow Up (yr)	Inclusion Criteria	Primary Endpoint	Rate Control Pts (%) (primary endpoint)	Rhythm Control Pts (%) (primary endpoint)	P value
AFFIRM (42)	4060	69.7	3.5	PAF or Persistent AF; ≥65 y/o or risk for stroke or death	Overall mortality	310/2027 (25.9)	356/2033 (26.7)	0.08
RACE (41)	522	68	2.3	Persistent AF or Flutter < 1 yr duration and 1 or 2 CV over 2 yr and oral anticoagulation	Composite: Cardiovascular death; CHF; Severe bleeding; PM implantation; Thromboembolic events; Severe adverse effects of AAD	44/256 (17.2)	60/266 (22.6)	0.11
PIAF (40)	252	61	1.0	Persistent AF (7-360 days)	Symptom improvement	76/125 (60.8)	70/127 (55.1)	0.317
STAF (39)	200	66	1.6	Persistent AF (> 4 weeks and < 2 yrs); LA size > 45mm; CHF NYHA II to IV; LVEF < 45%	Composite: Overall mortality; Cerebrovascular complications; CPR; Embolic events	10/100 (10%)	9/100 (9%)	0.99
PAF2 (38)	137	68	1.3	Symptomatic PAF (> 1 yr); Failure of ≥ 3 AAD; > 50 y/o; AVJ ablation	AAD are able to prevent development of permanent AF in long term F/U		57% relative reduction rate of risk of permanent AF	

Limitations of AFFIRM trial

1. Not comparison of sinus rhythm and AF, compared rate control to rhythm control
2. ‘on-treatment” analysis : 47% mortality reduction in sinus rhythm along with warfarin
3. Study population

   - high risk thromboembolic events
   - few congestive heart failure, young patients

Relationships Between Sinus Rhythm, Treatment, and Survival in the Atrial Fibrillation Follow-Up Investigation of Rhythm Management (AFFIRM) Study

The AFFIRM Investigators*

Background—The AFFIRM Study showed that treatment of patients with atrial fibrillation and a high risk for stroke or death with a rhythm-control strategy offered no survival advantage over a rate-control strategy in an intention-to-treat analysis. This article reports an "on-treatment" analysis of the relationship of survival to cardiac rhythm and treatment as they changed over time.

Methods and Results—Modeling techniques were used to determine the relationships among survival, baseline clinical variables, and time-dependent variables. The following baseline variables were significantly associated with an increased risk of death: increasing age, coronary artery disease, congestive heart failure, diabetes, stroke or transient ischemic attack, smoking, left ventricular dysfunction, and mitral regurgitation. Among the time-dependent variables, the presence of sinus rhythm (SR) was associated with a lower risk of death, as was warfarin use. Antiarrhythmic drugs (AADs) were associated with increased mortality only after adjustment for the presence of SR. Consistent with the original intention-to-treat analysis, AADs were no longer associated with mortality when SR was removed from the model.

Conclusions—Warfarin use improves survival. SR is either an important determinant of survival or a marker for other factors associated with survival that were not recorded, determined, or included in the survival model. Currently available AADs are not associated with improved survival, which suggests that any beneficial antiarrhythmic effects of AADs are offset by their adverse effects. If an effective method for maintaining SR with fewer adverse effects were available, it might be beneficial. (*Circulation*. 2004;109:1509-1513.)

Key Words: antiarrhythmia agents ■ anticoagulants ■ arrhythmia ■ fibrillation

CATHOLIC UNIVERSITY OF KOREA

Relationships Between Sinus Rhythm, Treatment, and Survival in the Atrial Fibrillation Follow-Up Investigation of rhythm Management (AFFIRM) Study

- The association of SR but not AADs with improved survival may reflect the fact that currently available AADs are neither highly efficacious nor completely safe.

- These results suggest that if an effective method for maintaining SR with fewer adverse effects were available, it might improve survival.

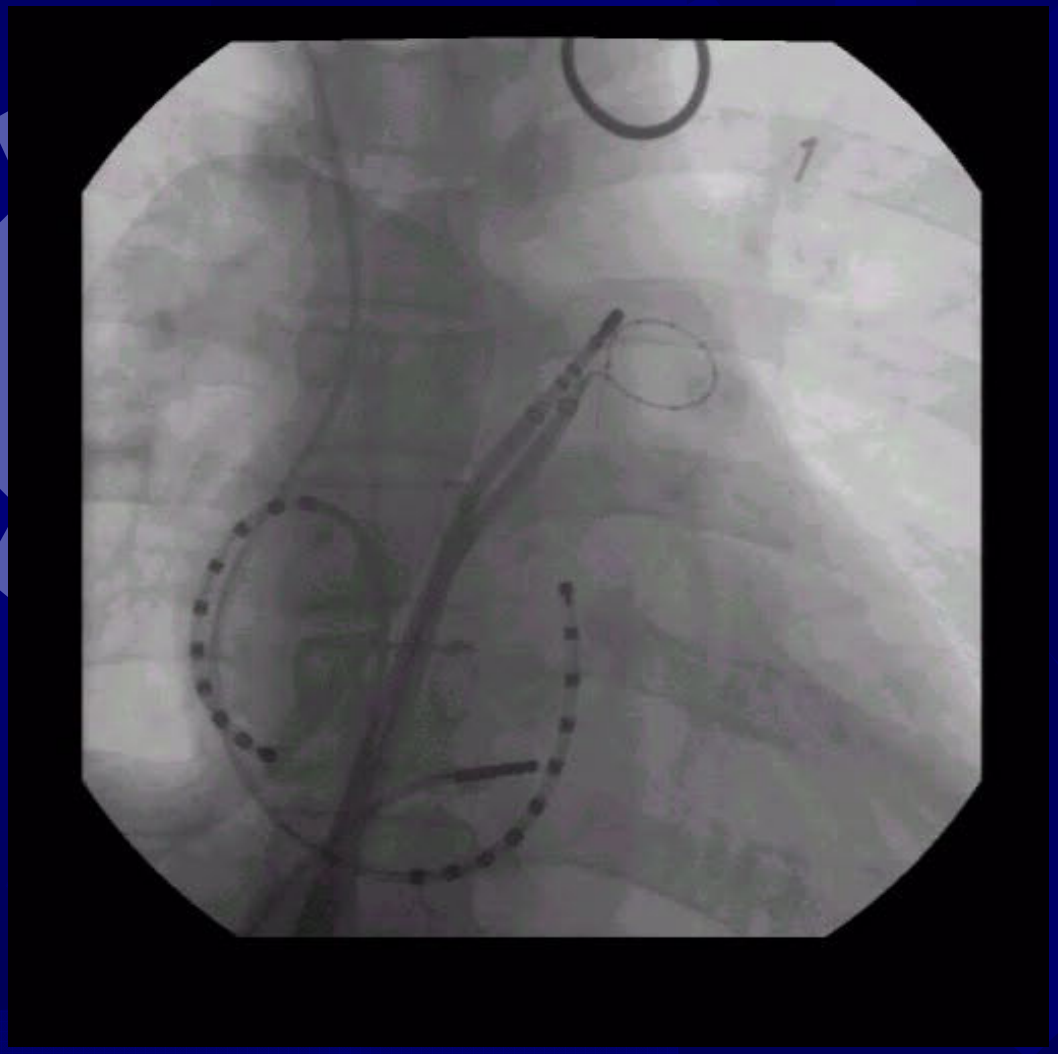
"If rhythm control is selected, what is the role for curative ablation procedures and how do they work?"

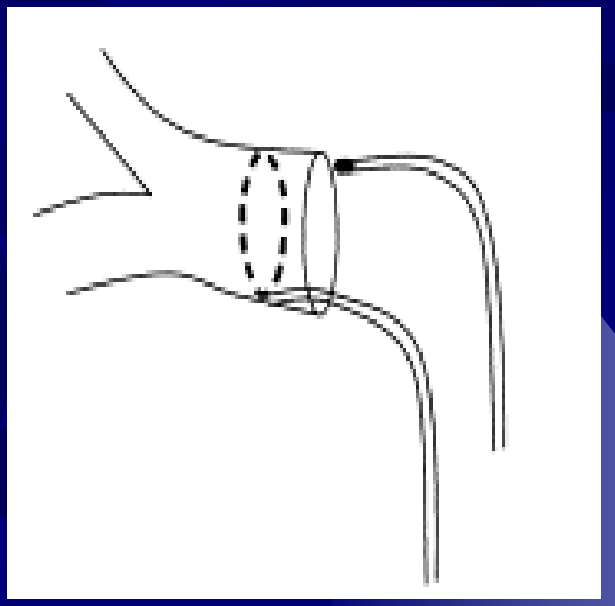
AF ablation therapy

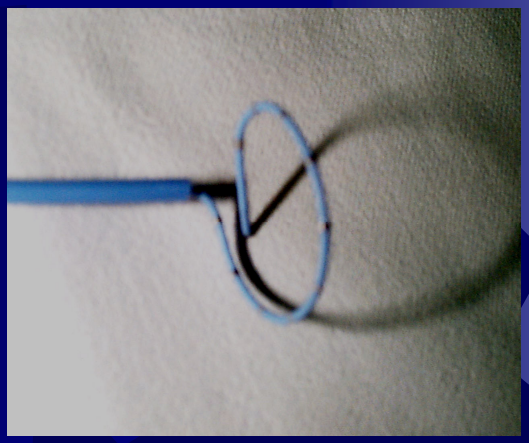
- PVs play a major role in both triggering and maintaining AF,
- AF including adolescents and, adults with structural heart disease
- disconnect PVs from the rest of atrium
- 1) Pulmonary vein isolation and
  2) circumferential left antrial ablation

Limitations of AF ablation is ‘uncertain technique and high complications’

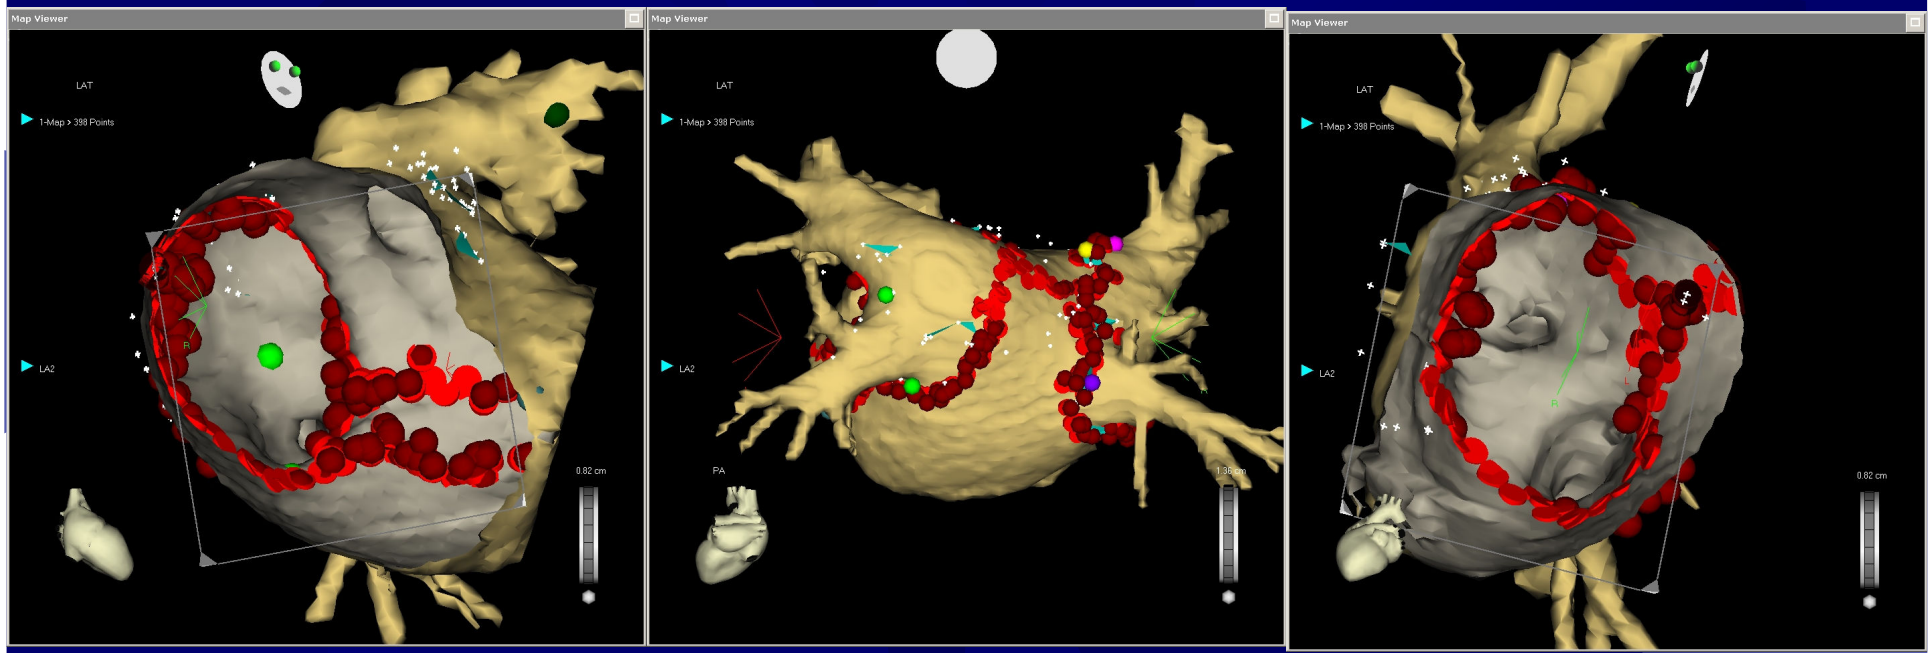
Pulmonary vein isolation







Substrate-guided ablation



Left endoscopic view

PA

Right endoscopic view

CATHOLIC UNIVERSITY OF KOREA

Substrate-guided ablation

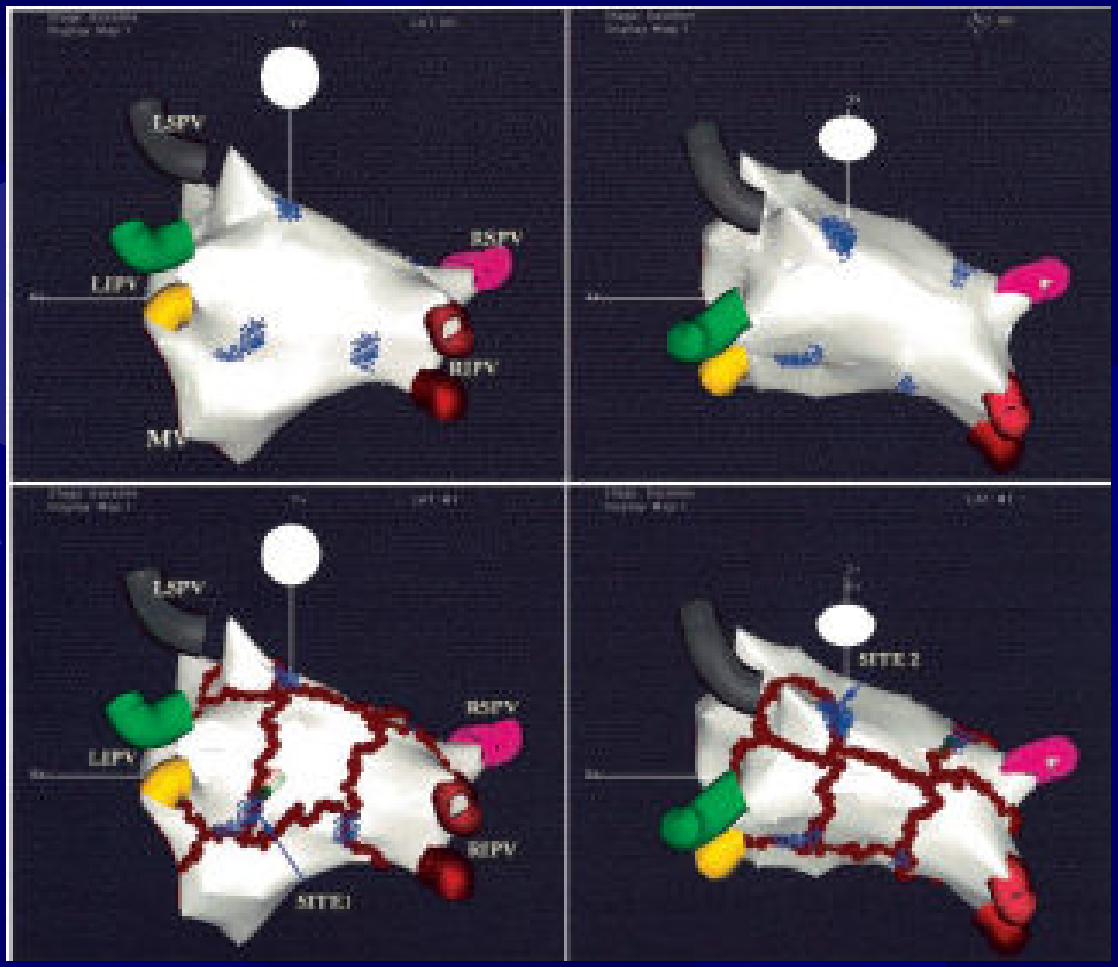
- Target key atrial regions responsible for perpetuating AF rather than targetting the trigger

  "pivot' points, "rotar" points
- Nademanee et al, JACC 43(11), 2004
- Targeting CFAE during AF

  - fragmented electrogram composed of 2 deflections or more and continous deflection of baseline

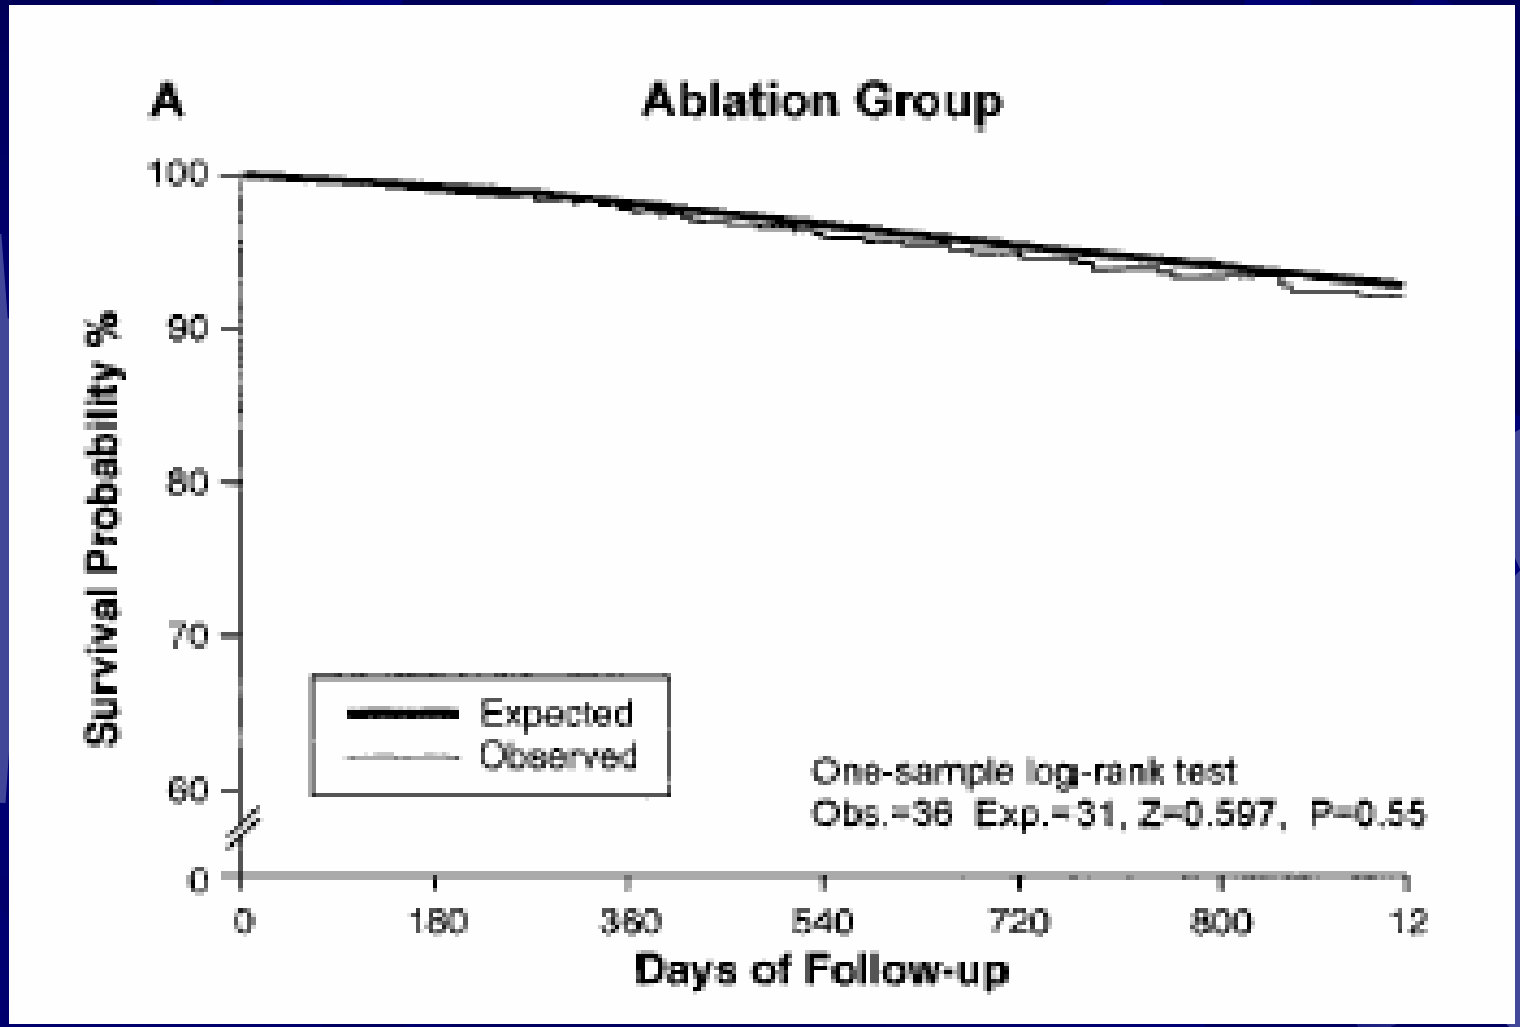
  - Atrial EGMs with very short CL < 120ms

Ablation Vagal Input

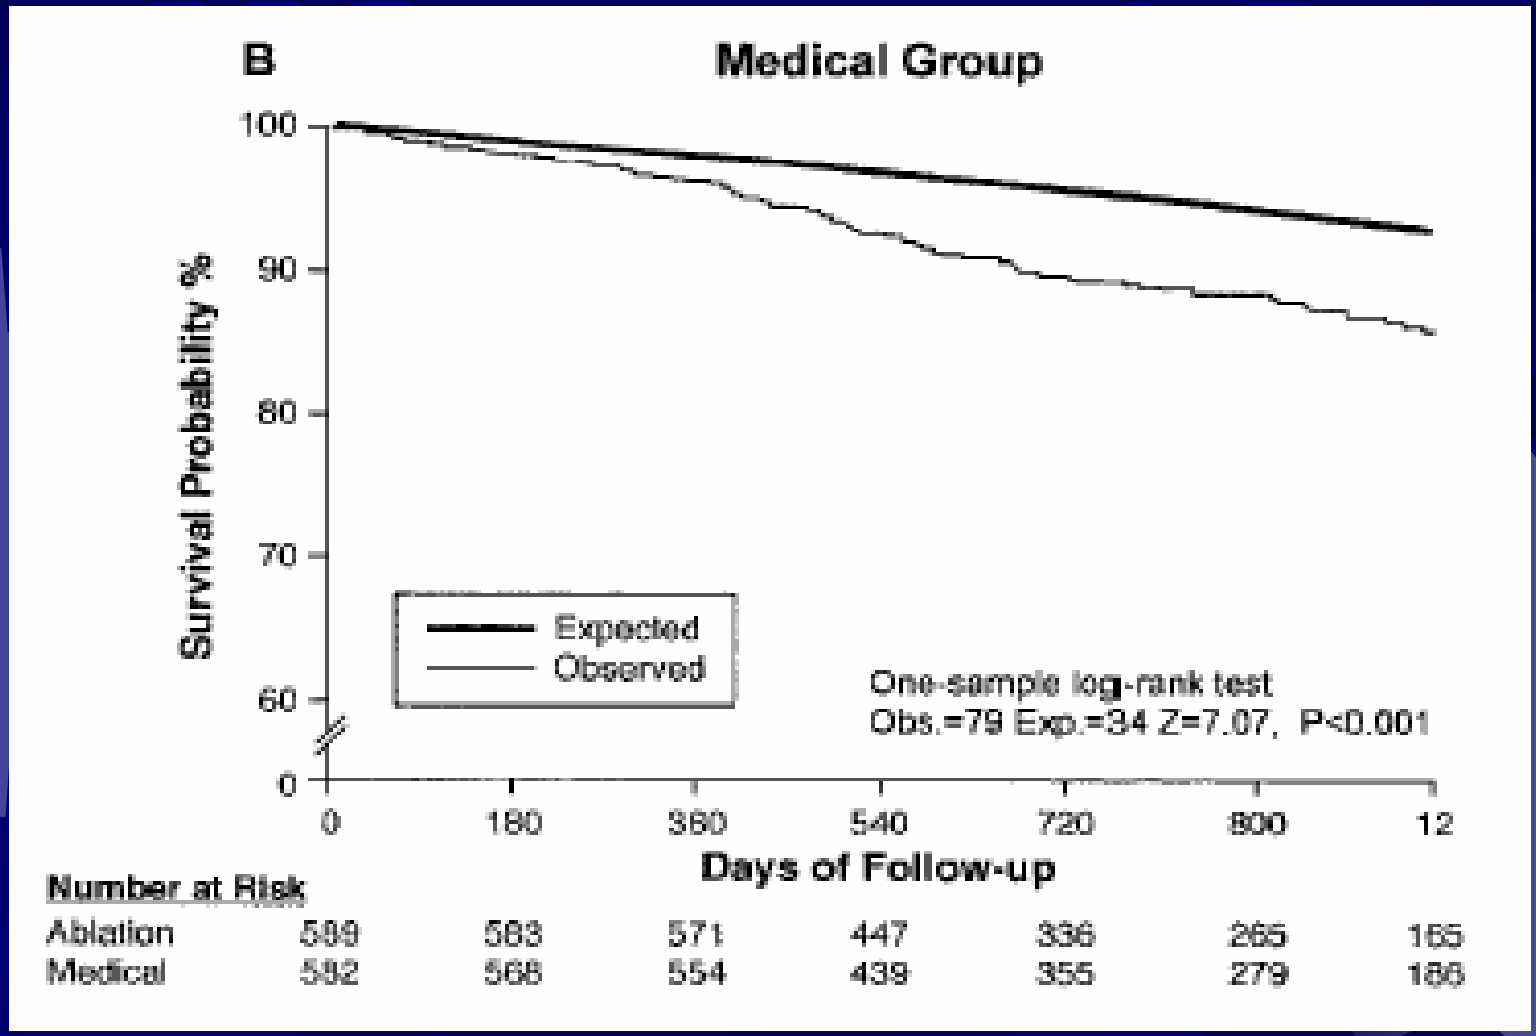


Pappone et al, Circulation 2004

- The cure rate off drug is 80.5% overall.
- 10-25% become responsive to previously ineffective drugs
- 2-3 folds better than antiarrhythmic drugs



Pappone et al, *J Am Coll Cardiol, 2003*



Pappone et al, *J Am Coll Cardiol, 2003*

Complications of AF ablation

- CVA : 0.5% (12/2425)
- Severe PV stenosis : 0.7% (16/2425)
- Hematoma : 0.8% (19/2425)
- Tamponade : 0.3% (8/2425)

Progression to chronic atrial fibrillation after the initial diagnosis of paroxysmal atrial fibrillation: Results from the Canadian Registry of Atrial Fibrillation

Charles R. Kerr, MD,[a] Karin H. Humphries, DSc,[a] Mario Talajic, MD,[b] George J. Klein, MD,[c] Stuart J. Connolly, MD,[d] Martin Green, MD,[e] John Boone, MD,[a] Robert Sheldon, MD, PhD,[f] Paul Dorian, MD,[g] and David Newman, MD[g] *Vancouver, British Columbia, Montreal, Quebec, London, Hamilton, Ottawa, and Toronto, Ontario, and Calgary, Alberta, Canada*

Background After its initial diagnosis, atrial fibrillation (AF) may progress from paroxysmal to chronic AF (CAF). The rate of progression and risk factors for progression are not clearly defined.

Methods The Canadian Registry of Atrial Fibrillation (CARAF) enrolled patients from 6 Canadian cities at the time of their first electrocardiographic diagnosis of AF. Comprehensive clinical and echocardiographic data were collected and patients were followed annually, carefully documenting clinical outcomes, recurrence of paroxysmal AF, and progression to CAF. Baseline clinical, electrocardiographic, and echocardiographic variables were evaluated by univariate Cox proportionate hazards analysis. A stepwise approach was used to model the association between echocardiographic and clinical variables with progression to CAF.

Results A total of 757 patients with a baseline diagnosis of paroxysmal AF were evaluated. Median follow-up was 8.0 years (range 2 days to 11.1 years). The probability of progression to CAF by 1 year was 8.6% and thereafter there was a slow but steady progression to 24.7% by 5 years. By 5 years, the probability of documented recurrence of any AF (chronic or paroxysmal) was 63.2%. Increasing age, significant aortic stenosis or mitral regurgitation, left atrial enlargement, and diagnosis of cardiomyopathy were independently associated with progression to CAF. A more rapid heart rate during AF was associated with decreased risk of progression.

Conclusions After the initial diagnosis of paroxysmal AF, there is a slow but steady progression to CAF. Baseline echocardiographic variables, age, cardiomyopathy, and heart rate were independently associated with progression to CAF.
(Am Heart J 2005;149:489-96.)

Long-Term Prognosis of Patients With Paroxysmal Atrial Fibrillation Depends on Their Response to Antiarrhythmic Therapy

Takashi Komatsu, MD; Shin Nakamura, MD; Osamu Suzuki, MD;
Daisuke Horiuchi, MD; Kunihiko Yomogida, MD; Ken Okumura, MD*

Background The rhythm control treatment strategy for persistent atrial fibrillation (AF) has been shown not to improve quality of life or prognosis any more than rate control. It is unclear whether the prognosis of the patients with paroxysmal AF (PAF) is influenced by the response to antiarrhythmic drug therapy (AAT).

Methods and Results The relationship between the response to AAT and long-term prognosis was evaluated in 290 patients with PAF (mean age, 69 years). During a mean follow-up period of 51 months, 114 patients (39%) had no recurrence of AF (Group 1), 113 (39%) had repeated AF recurrence (Group 2), and the remaining 63 (22%) had permanent AF despite AAT (Group 3). The survival rate without any cardiovascular deaths at 60 months was 99% in Group 1, 95% in Group 2 and 94% in Group 3 (p=NS among 3 groups). Survival rate without symptomatic ischemic stroke was 99% in Group 1, 88% in Group 2 and 76% in Group 3 ($p<0.05$ Group 1 vs Groups 2 and 3). The annual rate of stroke in the patients with warfarin treatment was similar among the 3 groups, whereas that in the patients without warfarin was higher in Groups 2 and 3 than in Group 1.

Conclusions Long-term prognosis of patients with PAF varies with the response to AAT: When sinus rhythm is maintained, the prognosis is good even without anticoagulation therapy. (*Circ J* 2004; **68:** 729–733)

Primary cure rate	83.7%	71.9%	0.01
Secondary cure rate	96.4%	87.6%	0.027

“ It seems to be reasonable that ablation be moved up to first-line therapy for some patients”

Indications of first-line ablation therapy

1. Those patients with symptomatic AF, who have high risk of conversion to chronic AF.
   1) mild to moderate structural heart disease,
   2) old age with good performance,
   3) heavy alcohol drinker and
   4) big LA size.

2. Younger patients with lone AF who are frequently symptomatic and very long term antiarrhythmic and poses higher risks and lifestyle costs

CATHOLIC UNIVERSITY OF KOREA

Which is the better strategy for atrial fibrillation rhythm control or rate control?

Conditions Favoring Rhythm over Rate Control in Patients with A Fib

Definite

Significant symptoms during good rate control

Hemodynamic compromise during good rate control

Younger patients with potential for decades of A Fib

Possible

Conditions that predispose to future diastolic compliance problems (e.g. HCM)

"Middle-aged" patients with acceptable symptoms during good rate control
