Case: Patient information

- **Chief complaint: Dyspnea aggravation for several months**
- **Present illness:**
 - 03': High BP & Hypertensive nephropathy diagnosed
 - HD start
 - 05': Sick Sinus Syndrome was diagnosed
 - DDD type pacemaker Implantation
 - 07' May: AF was diagnosed
 - Pacemaker mode change
 - 08' Feb.: DOE aggravation
 - DC cardioversion, Mode change to DDD
 - 09' Jan.: dyspnea aggravation
- **Past history**
 - DM (-), BP (+), stage IV chronic kidney disease on hemodialysis
- **Social history**
 - Smoking (-), alcohol (-)

MADIT-CRT: CONCLUSIONS

- **CRT reduces the risk of heart failure/death in NYHA class I/II pts. with low EF and wide QRS**
- **Women obtain a significantly greater benefit from CRT-D than men**
- **Improvement in cardiac substrate with CRT-D associated with reduction in VT/VF**
- **Patients with LBBB obtain the best benefit from CRT-D with marked reduction in heart failure and death during 30 months of follow-up**

Current Guidelines for CRT-D Therapy

- **Established**
 - **EF \leq 35%**
 - **NYHA III or ambulatory NYHA IV**
 - **QRS \geq 120ms**
 - **sinus rhythm**
- **New FDA Approval (MADIT-CRT Criteria)**
 - **EF \leq 30%, NYHA I/II, QRS \geq 130ms, and LBBB**

The Influence of Left Ventricular Ejection Fraction on the Effectiveness of Cardiac Resynchronization Therapy

MADIT-CRT (Multicenter Automatic Defibrillator Implantation Trial With Cardiac Resynchronization Therapy)

Valentina Kutiyfa, MD,*† Axel Kloppe, MD,‡ Wojciech Zareba, MD, PhD,* Scott D. Solomon, MD,§ Scott McNitt, MS,* Slava Polonsky, MS,* Alon Barsheshet, MD,* Bela Merkely, MD, PhD,† Bernd Lemke, MD,‡ Vivien Klaudia Nagy, MD,† Arthur J. Moss, MD,* Ilan Goldenberg, MD*
Rochester, New York; Budapest, Hungary; Bochum, Germany; and Boston, Massachusetts

Objectives	The goal of this study was to evaluate the influence of left ventricular (LV) lead position on the risk of ventricular tachyarrhythmia in patients undergoing cardiac resynchronization therapy (CRT).
Background	Left ventricular ejection fraction (LVEF) is a surrogate marker of heart failure (HF) status and associated risk. Data on the effectiveness of cardiac resynchronization therapy with defibrillator (CRT-D) in patients with mild HF and better LVEF are limited.
Methods	In the MADIT-CRT (Multicenter Automatic Defibrillator Implantation Trial With Cardiac Resynchronization Therapy) study, the echocardiography core laboratory assessed baseline LVEF independent of the enrolling centers and identified a range of LVEFs, including those >30% (i.e., beyond the eligibility criteria). Echocardiographic response with CRT, defined as percent change in left ventricular end-diastolic volume (LVEDV), was analyzed in 3 prespecified LVEF groups: >30%, 26% to 30%, and ≤25%. The primary endpoint was HF or death. Secondary endpoint included all-cause mortality.
Results	LVEF was evaluated in 1,809 study patients. There were 696 (38%) patients with LVEF >30% (in the range of 30.1% to 45.3%); 914 patients (50.5%) with LVEF 26% to 30%; and 199 patients with LVEF ≤25% (11%). The mean reduction in LVEDV with CRT-D therapy at the 1-year follow-up was directly related to increasing LVEF (LVEF >30%: 22.3%; LVEF 26% to 30%: 20.1%; and LVEF ≤25%: 18.7% reduction, respectively [p = 0.001]). CRT-D treatment similarly reduced the risk of HF/death in patients with LVEF >30% (hazard ratio [HR]: = 0.56 [95% confidence interval (CI): 0.39 to 0.82], p = 0.003), LVEF 26% to 30% (HR: 0.67; [95% CI: 0.50 to 0.90], p = 0.007), and LVEF ≤25% (HR: 0.57 [95% CI: 0.35 to 0.95], p = 0.03; all p values for LVEF-by-treatment interactions >0.1).
Conclusions	In MADIT-CRT, the clinical benefit of CRT was evident regardless of baseline LVEF, including those with LVEF >30%, whereas the echocardiographic response was increased with increasing LVEF, indicating that CRT might benefit patients with better LVEF. (Multicenter Automatic Defibrillator Implantation With Cardiac Resynchronization Therapy [MADIT-CRT]; NCT00180271) (J Am Coll Cardiol 2013;61:936-44) © 2013 by the American College of Cardiology Foundation

Further adjusted for age, diabetes mellitus, hypertension, left ventricular end systolic volume indexed to body surface area and resynchronization treatment. *Fast ventricular tachycardia (VT) was defined as a VT with a cycle length <320 ms. †Per 5% increase in baseline left ventricular ejection fraction.

CI = confidence interval; HR = hazard ratio; VF = ventricular fibrillation.

Predictors of Super-Response to Cardiac Resynchronization Therapy and Associated Improvement in Clinical Outcome

The MADIT-CRT (Multicenter Automatic Defibrillator Implantation Trial With Cardiac Resynchronization Therapy) Study

Jonathan C. Hsu, MD,* Scott D. Solomon, MD,† Mikhail Bourgoun, MD,† Scott McNitt, MS,‡
Ilan Goldenberg, MD,‡ Helmut Klein, MD,‡ Arthur J. Moss, MD,‡ Elyse Foster, MD,*
on behalf of the MADIT-CRT Executive Committee

San Francisco, California; Boston, Massachusetts; and Rochester, New York

- Objectives** The authors investigated predictors of left ventricular ejection fraction (LVEF) super-response to cardiac resynchronization therapy with defibrillator (CRT-D) and whether super-response translated into improved event-free survival in patients with mildly symptomatic heart failure (HF).
- Background** Few data exist on predictors of super-response to CRT-D and associated morbidity and mortality in mildly symptomatic HF populations.
- Methods** Patients were assigned to CRT-D with paired echocardiograms at baseline and at 12 months (n = 752). Super-response was defined by the top quartile of LVEF change. Best-subset regression analysis identified predictors of LVEF super-response. Kaplan-Meier survival analysis and Cox proportional hazards regression were performed to investigate associations of response category with development of nonfatal HF event or all-cause death.
- Results** All 191 super-responders experienced an LVEF increase of $\geq 14.5\%$ (mean LVEF increase $17.5 \pm 2.7\%$). Six predictors were associated with LVEF super-response to CRT-D therapy: female sex (odds ratio [OR]: 1.96; p = 0.001), no prior myocardial infarction (OR: 1.80; p = 0.005), QRS duration ≥ 150 ms (OR: 1.79; p = 0.007), left bundle branch block (OR: 2.05; p = 0.006), body mass index < 30 kg/m² (OR: 1.51; p = 0.035), and smaller baseline left atrial volume index (OR: 1.47; p < 0.001). Cumulative probability of HF or all-cause death at 2 years was 4% in super-responders, 11% in responders, and 26% in hypo-responders (log-rank p < 0.001 overall). In multivariate analysis, hyporesponse was associated with increased risk of HF or all-cause death, compared with super-response (hazard ratio: 5.25; 95% confidence interval: 2.01 to 13.74; p = 0.001).
- Conclusions** Six baseline factors predicted LVEF super-response in CRT-D-treated patients with mild HF. Super-response was associated with reduced risk of subsequent cardiac events. (Multicenter Automatic Defibrillator Implantation Trial With Cardiac Resynchronization Therapy [MADIT-CRT]; NCT00180271) (J Am Coll Cardiol 2012;59:2366–73) © 2012 by the American College of Cardiology Foundation
