- Normal coronary arteries on angiography

- At least one cardiovascular risk factor
- More common in women than in men
- Approximately 50% of these patients have physiologic evidence of microvascular coronary dysfunction

Limitation of Diagnosis of Microvascular Angina

- No recognition
- No vaso- or coronary reactivity test
- Subjective diagnosis
- Slow flow
- Specific hospital bias
- Co-existing mild coronary stenosis (<50%)
or myocardial bridging

Summary

In women,

- Aging is the most strong factor for IHD.
- Considerable patients may have microvascular angina.
- Impairment of LV diastolic function may have some relation to microvascular angina.
- Additional studies with specific diagnostic testing are required.
