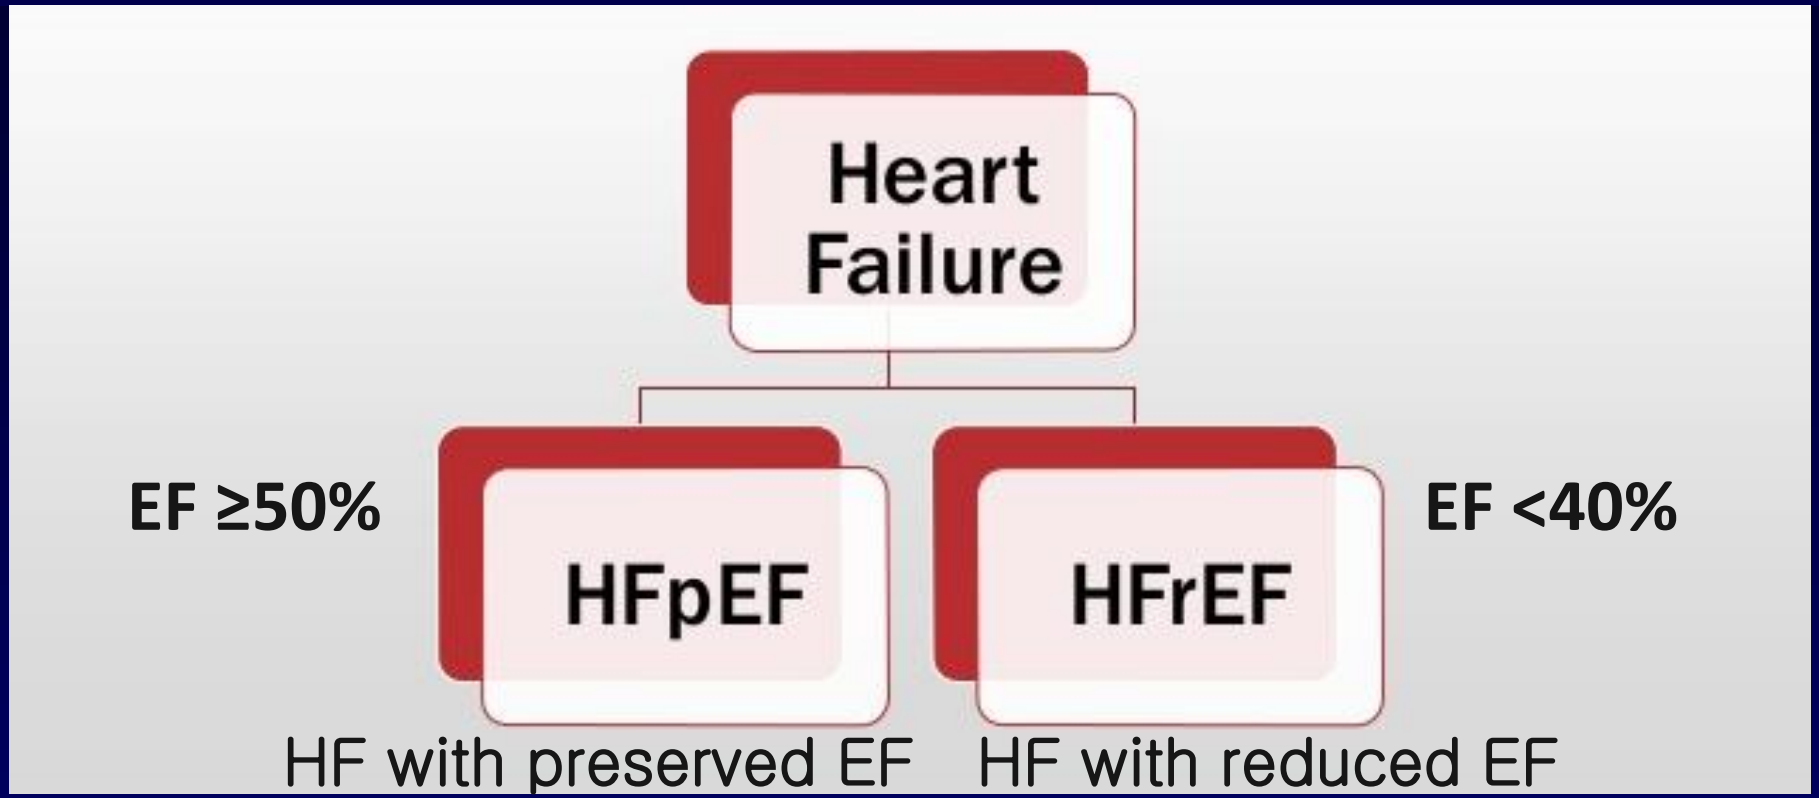
Introduction

Classic Classification



Type of HF		HFrEF	HFmrEF	HFpEF
CRITERIA	1	Symptoms ± Signs[a]	Symptoms ± Signs[a]	Symptoms ± Signs[a]
	2	LVEF <40%	LVEF 40–49%	LVEF ≥50%
	3	–	1. Elevated levels of natriuretic peptides[b]; 2. At least one additional criterion: a. relevant structural heart disease (LVH and/or LAE), b. diastolic dysfunction (for details see Section 4.3.2).	1. Elevated levels of natriuretic peptides[b]; 2. At least one additional criterion: a. relevant structural heart disease (LVH and/or LAE), b. diastolic dysfunction (for details see Section 4.3.2).

2016 ESC guidelines for HF: Eur Heart J 2016;37(27):2129-200

What is HF with recovered EF?

- Heart failure
- Current LVEF ≥ 40 or 50%
- Any previously documented LVEF < 40 or 50%

- Should not be classified with HFpEF (HF with preserved EF)

Punnoose et al. JCF 2011;17:527-532
Basuray et al. Circulation 2014;129:2380-2387
Kalogeropoulos et al. JAMA cardiology 2016;1:510-518

Nomenclature: What is the right word?

- HF with recovered EF = HFrecEF
- HF with improved EF
- HF with better EF

Punnoose et al. JCF 2011;17:527-532
Basuray et al. Circulation 2014;129:2380-2387

U–Penn Heart Failure Cleveland

Heart Failure With Recovered Ejection Fraction

Clinical Description, Biomarkers, and Outcomes

Anupam Basuray, MD, MPH; Benjamin French, PhD; Bonnie Ky, MD, MSCE; Esther Vorovich, MD; Caroline Olt, BA; Nancy K. Sweitzer, MD, PhD; Thomas P. Cappola, MD, ScM; James C. Fang, MD

Background—We hypothesized that patients with heart failure (HF) who recover left ventricular function (HF-Recovered) have a distinct clinical phenotype, biology, and prognosis compared with patients with HF with reduced ejection fraction (HF-REF) and those with HF with preserved ejection fraction (HF-PEF).

Methods and Results—The Penn Heart Failure Study (PHFS) is a prospective cohort of 1821 chronic HF patients recruited from tertiary HF clinics. Participants were divided into 3 categories based on echocardiograms: HF-REF if EF was <50%, HF-PEF if EF was consistently ≥50%, and HF-Recovered if EF on enrollment in PHFS was ≥50% but prior EF was <50%. A significant portion of HF-Recovered patients had an abnormal biomarker profile at baseline, including 44% with detectable troponin I, although in comparison, median levels of brain natriuretic factor, soluble fms-like tyrosine kinase receptor-1, troponin I, and creatinine were greater in HF-REF and HF-PEF patients. In unadjusted Cox models over a maximum follow-up of 8.9 years, the hazard ratio for death, transplantation, or ventricular assist device placement in HF-REF patients was 4.1 (95% confidence interval, 2.4–6.8; $P<0.001$) and in HF-PEF patients was 2.3 (95% confidence interval, 1.2–4.5; $P=0.013$) compared with HF-Recovered patients. The unadjusted hazard ratio for cardiac hospitalization in HF-REF patients was 2.0 (95% confidence interval, 1.5–2.7; $P<0.001$) and in HF-PEF patients was 1.3 (95% confidence interval, 0.90–2.0; $P=0.15$) compared with HF-Recovered patients. Results were similar in adjusted models.

Conclusions—HF-Recovered is associated with a better biomarker profile and event-free survival than HF-REF and HF-PEF. However, these patients still have abnormalities in biomarkers and experience a significant number of HF hospitalizations, suggesting persistent HF risk. (*Circulation*. 2014;129:2380-2387.)

Key Words: heart failure ■ myocardium ■ ventricular remodeling

Characteristics and Outcomes of Adult Outpatients With Heart Failure and Improved or Recovered Ejection Fraction

Andreas P. Kalogeropoulos, MD, MPH, PhD; Gregg C. Fonarow, MD; Vasiliki Georgiopoulou, MD, MPH, PhD; Gregory Burkman, MD; Sarawut Siwamogsatham, MD; Akash Patel, MD; Song Li, MD; Lampros Papadimitriou, MD, PhD; Javed Butler, MD, MPH, MBA

RESULTS The study cohort comprised 2166 participants. Their median age was 65 years, 41.4% (896 of 2166) were female, 48.7% (1055 of 2166) were white and 45.2% (1368 of 2166) black, and 63.2% (1368 of 2166) had coronary artery disease. Preserved (>40%) LVEF at inception was present in 816 of 2166 (37.7%) patients. Of these patients, 350 of 2166 (16.2%) had previously reduced (≤40%) LVEF and were classified as having HFrecEF, whereas 466 of 2166 (21.5%) had no previous reduced LVEF and were classified as having HFpEF. The remaining 1350 (62.3%) patients were classified as having HFrEF. After 3 years, age and sex–adjusted mortality was 16.3% in patients with HFrEF, 13.2% in patients with HFpEF, and 4.8% in patients with HFrecEF ($P < .001$ vs HFrEF or HFpEF). Compared with patients with HFpEF and patients with HFrEF, patients with HFrecEF had fewer all-cause (adjusted rate ratio [RR] vs HFpEF, 0.71; 95% CI, 0.55-0.91; $P = .007$), cardiovascular (RR, 0.50; 95% CI, 0.35-0.71; $P < .001$), and HF-related (RR, 0.48; 95% CI, 0.30-0.76; $P = .002$) hospitalizations and were less likely to experience composite end points commonly used in clinical trials (death or cardiovascular hospitalization and death or HF hospitalization).

CONCLUSIONS AND RELEVANCE Outpatients with HFrecEF have a different clinical course than patients with HFpEF and HFrEF, with lower mortality, less frequent hospitalizations, and fewer composite end points. These patients may need to be investigated separately in outcomes studies and clinical trials.

EXPOSURES Type of HF at baseline, classified as HF with reduced ejection fraction (HFrEF) (defined as current LVEF ≤40%), HF with preserved ejection fraction (HFpEF) (defined as current and all previous LVEF reports >40%), and HF with recovered ejection fraction (HFrecEF) (defined as current LVEF >40% but any previously documented LVEF ≤40%).

Received 20 October 2016; received in revised form 31 January 2017; accepted 9 February 2017; online published-ahead

Background To identify the predictors of left ventricular functional recovery (LV in acute heart failure (AHF) patients with newly diagnosed dilate

Methods A total of 175 consecutive patients with newly diagnosed DCM according to LVFR on follow-up echocardiography; the recover males) vs. the non-recovered group (n = 121, 60.5 ± 15.1 years, 7 cardiographic findings were compared, and major adverse cardia including death, rehospitalisation, and stroke were analysed.

The primary end-point was LVFR on follow-up echocardiography at six months after discharge from the index AHF. Left ventricular functional recovery was defined as LVEF ≥50% on follow-up echocardiography at six months in the present study [12]. The secondary end-point was the development of major adverse cardiac and cerebrovascular events (MACCE) during five years of clinical follow-up. Death, HF rehospitalisation, or stroke during clinical follow-up was defined as MACCE in the present study, and clinical follow-up ended in the case of death.

Incidence of HFrecEF in newly diagnosed DCM

Stimulant use	2 (6.5)	3 (3.7)	0	.30
High alcohol intake	6 (19.4)	8 (9.8)	2 (7.1)	.12
Arrhythmia	12 (38.7)	35 (42.7)	12 (42.9)	.84
TTNtv present, No./total No. (%)[f]	4/28 (14.3)	15/76 (19.7)	7/24 (29.2)	.44

Abbreviations: EF, ejection fraction; IQR, interquartile range; LVEF, left ventricular ejection fraction; TTNtv, titin truncating variant.

[a] Tests were performed using *t* test for age at diagnosis, Mann-Whitney test for worst LVEF and best LVEF, and Fisher exact test for all other clinical characteristics. All *P* values are for recovered EF vs the other 2 groups combined.

[b] For patients with nonrecovered EF or transplant, n = 88. Worst LVEF measures are always recorded pretransplant.

[c] n = 6.

[d] For patients with nonrecovered EF or transplant, n = 87. Best LVEF measures are always recorded pretransplant.

[e] n = 5.

[f] For TTNtv present, n = 128.

Prevalence of HFrecEF (Cross-sectional)

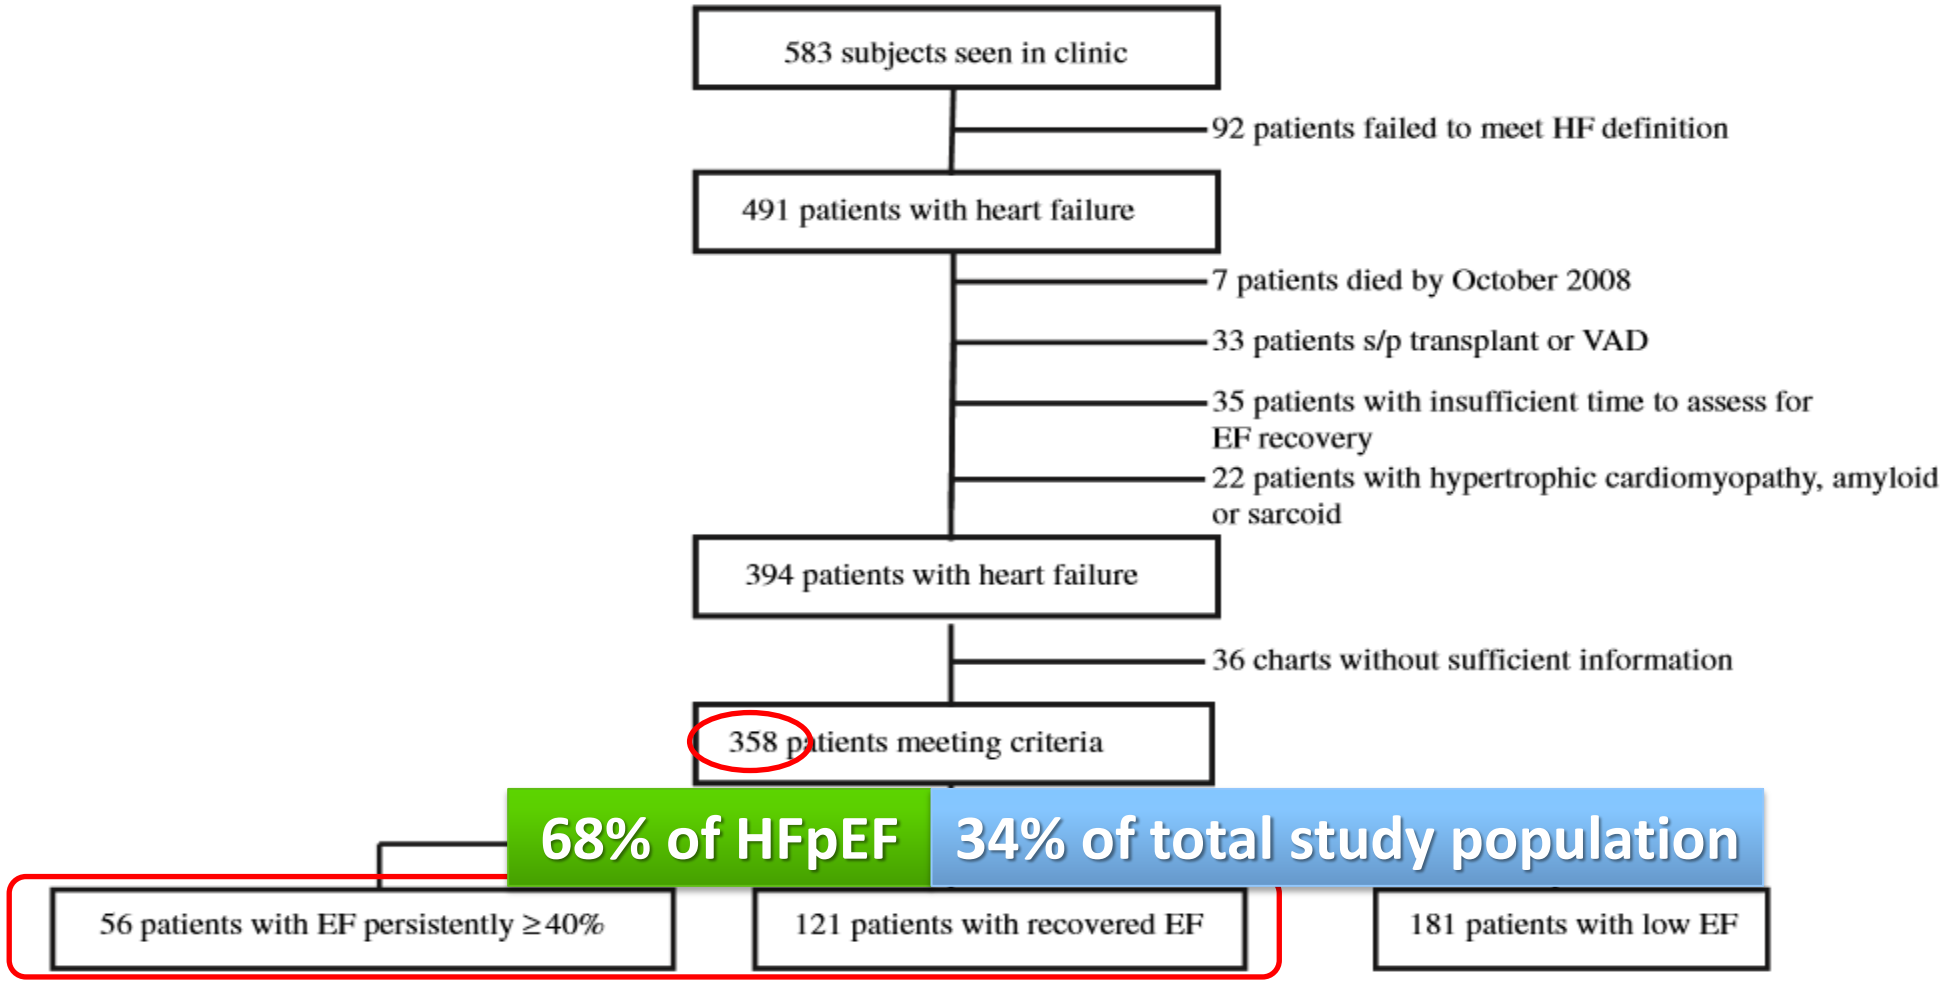

Fig. 1. Flow diagram of patient selection and classification. Of 583 consecutive patients initially screened, 358 patients met inclusion criteria and were sorted into 3 categories based on most recent and lowest measured ejection fraction (EF). HF, heart failure; VAD, ventricular assist device.

Limitation in restoration of global longitudinal strain

KSE 2016
The 41st Annual Scientific Meeting
November 19 Sat. ~ 20 Sun, 2016
Sheraton Grand Wakerhill Hotel, Seoul

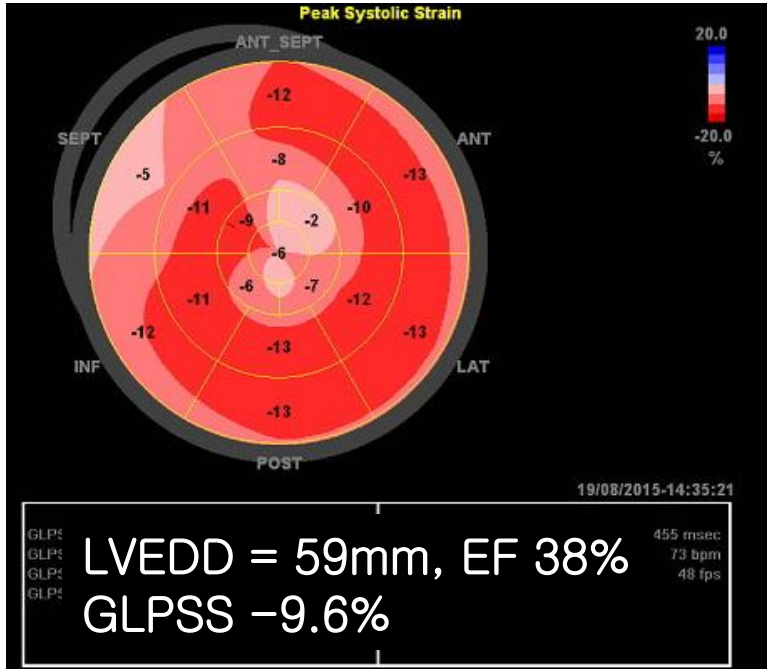
Global Longitudinal Strain is not Completely Recovered in Dilated Cardiomyopathy with Recovered Left Ventricular Ejection Fraction

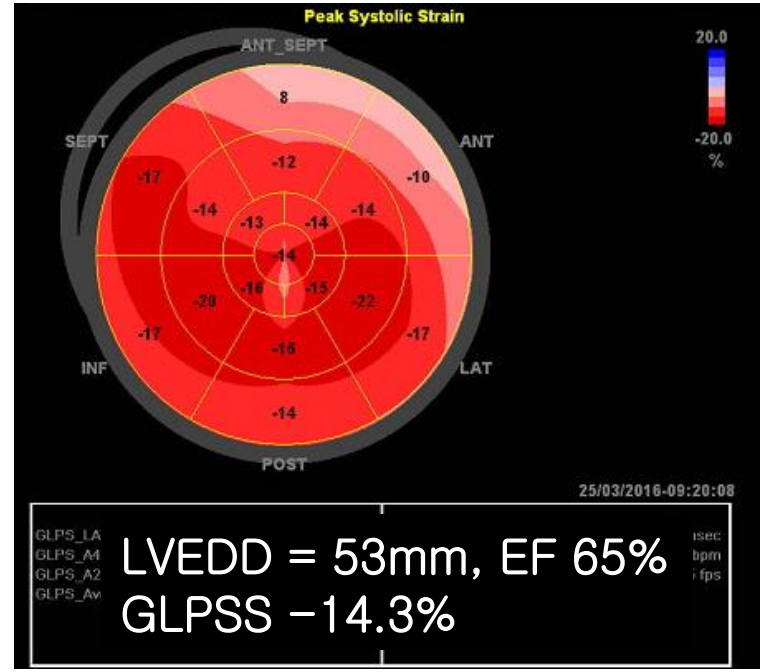
Jae Yeong Cho, Kye Hun Kim, Ji Eun Kim, Hyukjin Park, Hyun Ju Yoon, Jong Chun Park

Department of Cardiovascular Medicine, Chonnam National University Hospital, Gwangju, Republic of Korea

Results

- **Similarly, initial GLPSS was not different between groups (-8.6±3.7% vs. -7.9±3.3%, p=0.368), but FU GLPSS was better in the recovered group (-15.1±2.8 vs. -9.6±3.9, p <0.001).**





Cho, Kim et al. KSE 2016

Results

- **However, GLPSS in the recovered group was always worse than GLPSS in age- and sex-matched normal populations (-15.1±2.8 vs. -20.8±2.0, p<0.001).**

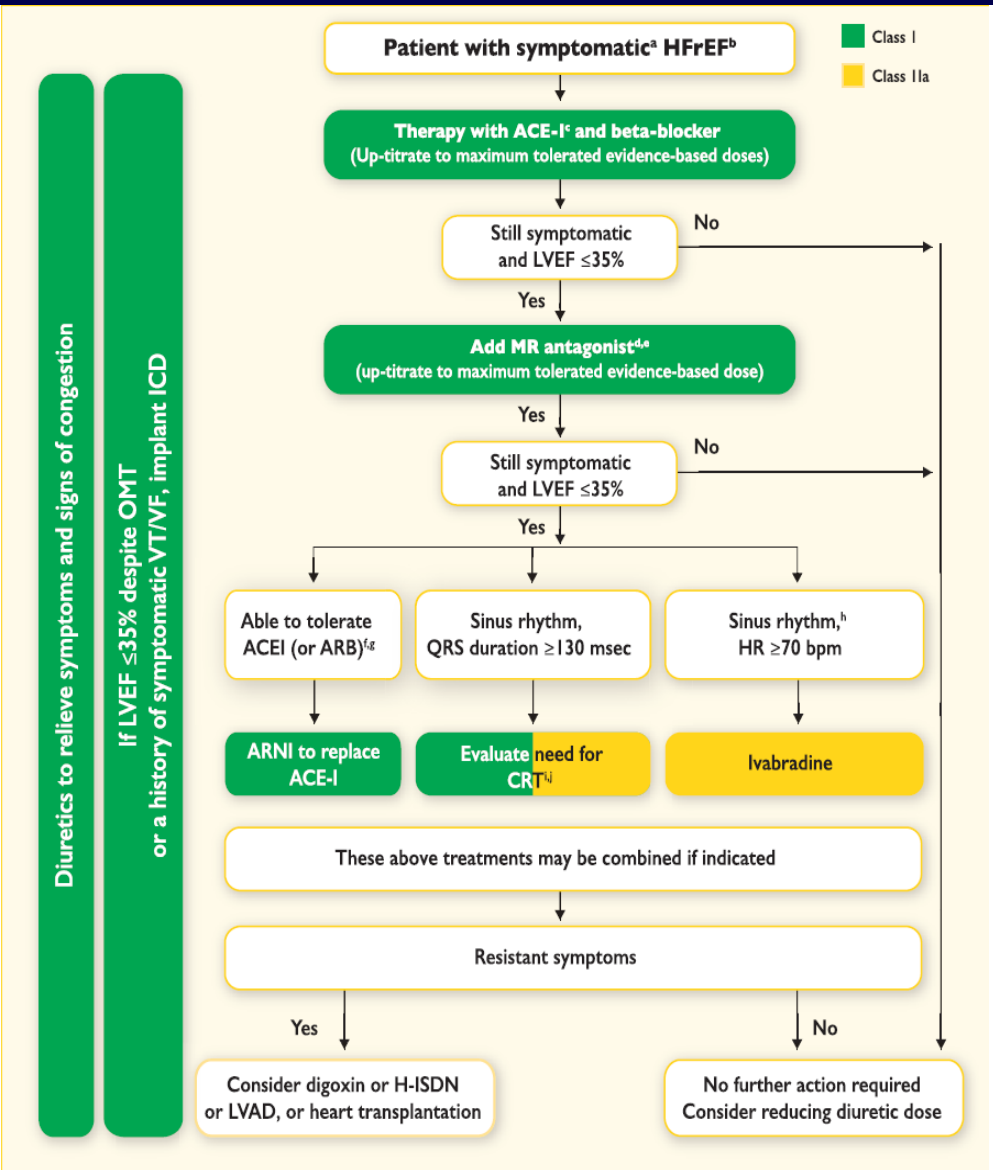
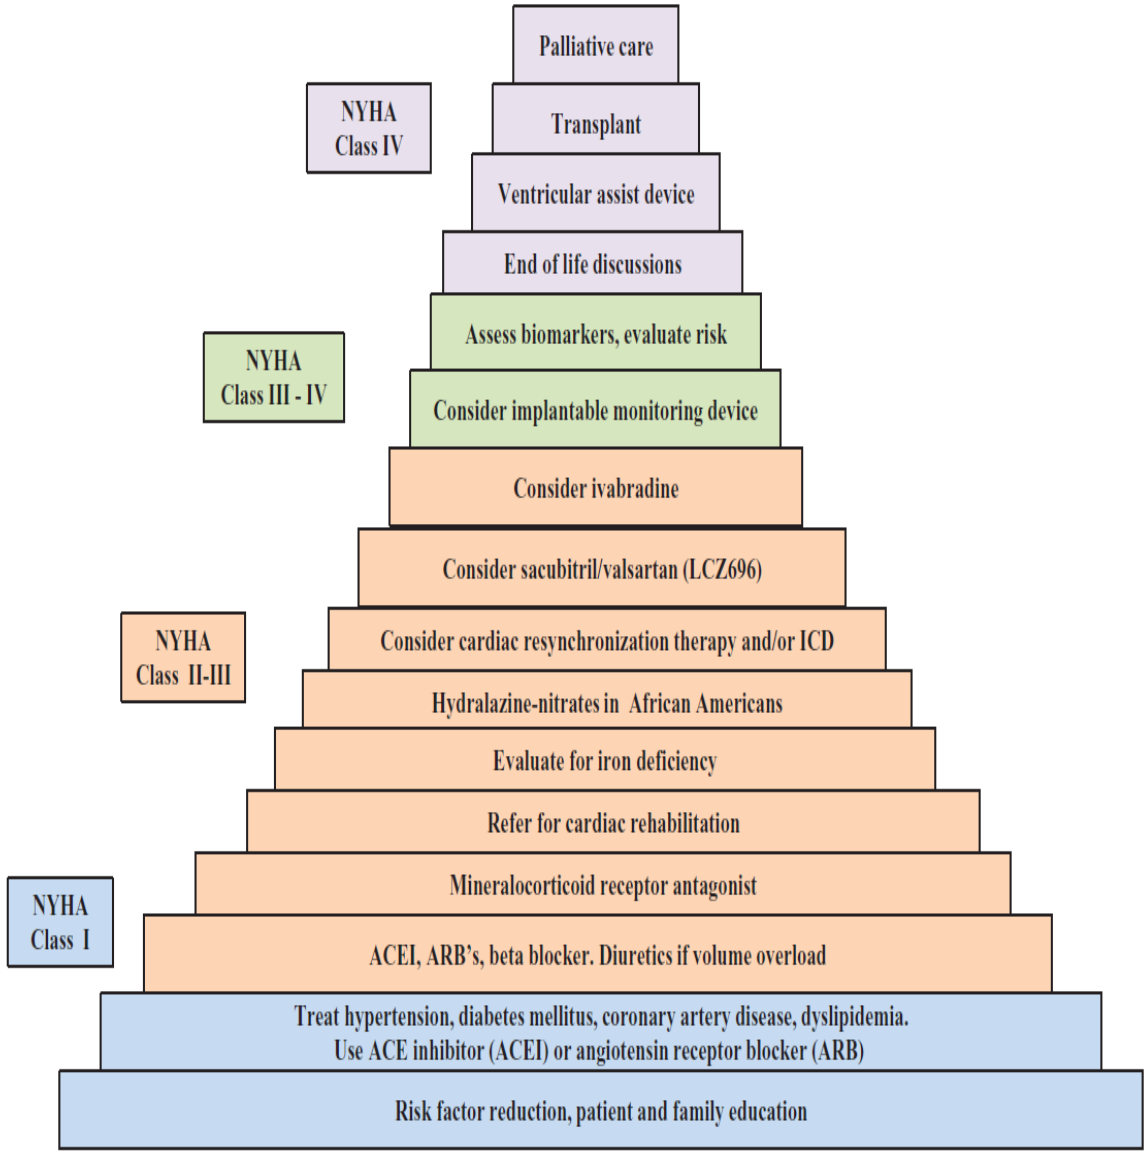
Management of HFrecEF

Title	Treating patients with ENTRESTO in daily clinical practice
Presenter(s)	Prof Faiez Zannad, France
Date	April 19, 2017, 13:00 hrs CEST
Description	Prof Zannad will discuss about a couple of patients with HF and the rationale for starting ENTRESTO, and the consequent outcomes.

"Statins, we don't know maybe lifelong. ACEi? We don't know. Trials just cover 1 or 2 years. You need to keep going for life."

Approach to the patients with HFrEF: Guidelines





2016 ESC guidelines for HF: Eur Heart J 2016;37(27):2129-200

No current guidelines about HFrecEF

are all used to achieve this objective.[1–6] However, little is known about the natural history, prognosis, and need for continued long-term therapies in patients when there is recovery of LV function (eg, HF and recovered ejection fraction [HF-Recovered]).[7–10] In fact, many of these patients continue HF-REF treatment, whereas others may discontinue therapy or become misclassified as having HF with preserved ejection fraction (HF-PEF).[11]

Basuray et al. Circulation. 2014;129:2380-2387

Guideline-based therapy 는 언제까지 필요한가?

- EF 호전 후 ACEi/ARB 나 BB 를 중단할 수 있을까?
- 약을 중단하면 반드시 재발하는가?
- 약을 중단하지 않아도 재발하는 비율은?
- BB를 중단하면 재발하는가?
- ACEi/ARB 를 중단하면 재발하는가?

Recovery and recurrence of left ventricular systolic dysfunction in patients with idiopathic dilated cardiomyopathy

Jeonggeun Moon MD, Young-Guk Ko MD, Namsik Chung MD, Jong-Won Ha MD, Seok-Min Kang MD, Eui-Young Choi MD, Se-Joong Rim MD

J Moon, Y-G Ko, N Chung, et al. Recovery and recurrence of left ventricular systolic dysfunction in patients with idiopathic dilated cardiomyopathy. Can J Cardiol 2009;25(5):e147-e150.

BACKGROUND: Some patients with nonischemic left ventricular (LV) systolic failure recover to have normal LV systolic function. However, few studies on the rates of recovery and recurrence have been reported, and no definitive indicators that can predict the recurrence of LV dysfunction in recovered idiopathic dilated cardiomyopathy (IDCMP) patients have been determined. It was hypothesized that patients who recovered from nonischemic LV dysfunction have a substantial risk for recurrent heart failure.
METHODS: Forty-two patients (32 men) with IDCMP (mean [± SD] age 56.9±8.7 years) who recovered from systolic heart failure (LV ejection fraction [LVEF] of 26.5±6.9% at initial presentation) to a near-normal state (LVEF of 40% or greater, and a 10% increase or greater in absolute value) were monitored for recurrence of LV systolic dysfunction. Patients with significant coronary artery disease were excluded. Patients were monitored for 41.0±26.3 months after recovery (LVEF 53.4±7.6%) from LV dysfunction.
RESULTS: LV systolic dysfunction reappeared (LVEF 27.5±8.1%) during the follow-up period in eight of 42 patients (19.0%). No significant difference between the groups with or without recurrent heart failure was observed in the baseline clinical and echocardiographic characteristics. However, more patients in the recurred IDCMP group than those in the group that maintained the recovery state had discontinued antiheart failure medication (62.5% versus 5.9%, P<0.05).
CONCLUSIONS: LV dysfunction recurs in some patients with reversible IDCMP. The recurrence was significantly correlated with the discontinuation of antiheart failure drugs. The results suggest that continuous medical therapy may be mandatory in patients who recover from LV systolic dysfunction.

Digoxin-associated mortality: a systematic review and meta-analysis of the literature

Mate Vamos, Julia W. Erath, and Stefan H. Hohnloser*

Department of Cardiology, Division of Clinical Electrophysiology, J.W. Goethe University, Theodor-Stern-Kai 7, 60590 Frankfurt am Main, Germany

Conclusions

This meta-analysis of the contemporary literature indicates that digoxin therapy particularly without proper serum level control is associated with an increased mortality risk in patients with AF and with CHF. Our sensitivity analysis, however, suggests negative effects of digoxin particularly in the AF population but somewhat less unfavourable effects in the CHF population. Coupled with the notion emphasized by Rathore *et al.*,[33] this calls for randomized trials of dose-adjusted digoxin therapy at least in CHF patients. Until such proper randomized controlled trials are being completed, digoxin should be used with great caution (including monitoring plasma levels), particularly when administered for rate control in AF.

ABSTRACT

Background: The appropriateness of repeat transthoracic echocardiography (TTE) for stable heart failure (HF) is based on timing of the follow-up examination, but this lacks scientific support. We sought the association of routine follow-up TTE on survival and readmission in stable HF.

Methods: Patients with HF were selected from consecutive HF admissions from 2008 to 2012. Groups were divided into: no follow-up TTE; routine <1 year with no change in status ("rarely appropriate"), ≥1 year follow-up with no change in status ("maybe appropriate") and TTE due to change in clinical status ("appropriate"). Survival analysis was performed for the combined endpoint of HF readmission and death, and a separate analysis was performed for HF readmission, with death as a competing risk.

Results: Of 550 HF patients, 141 had a follow-up TTE, including 41 (29%) within 1 year. The event-free time in years was similar between no TTE (1.10 years [95%CI: 0.69, 1.49], routine TTE <1 year (2.61 years [95% CI: 1.08, 3.04], routine >1 year (2.45 years [95% CI: 1.37, 5.78]); all were greater than symptomatic patients (0.09 years [95% CI: 0.02, 1.80]). HF readmission was independently associated with statins, renal disease, coronary angiography and NYHA class, but not follow-up TTE timing. There were no differences in the cumulative incidence for death between groups. There were no differences in change in management in routine TTE <1 year and ≥1 year.

Conclusion: The distinction of appropriateness of routine repeat TTE in stable HF patients, based on testing <1 or ≥1 year after index admission appears unjustified.

Fonseca, et al. Int J Cardiol 2017;230:619-624

Adverse events according to TTE FU type

- **Appropriate** – patients with FU TTE d/t a change in clinical status or cardiac exam.
- **Inappropriate** – routine F/U <1 year
- **Uncertain** – routine F/U ≥ 1 year
- **No-TTE** – patients with no follow-up TTE

Abbreviations: EF, ejection fraction; IQR, interquartile range; LVEF, left ventricular ejection fraction; TTNtv, titin truncating variant.

[a] Tests were performed using *t* test for age at diagnosis, Mann-Whitney test for worst LVEF and best LVEF, and Fisher exact test for all other clinical characteristics. All *P* values are for recovered EF vs the other 2 groups combined.

[b] For patients with nonrecovered EF or transplant, n = 88. Worst LVEF measures are always recorded pretransplant.

[c] n = 6.

[d] For patients with nonrecovered EF or transplant, n = 87. Best LVEF measures are always recorded pretransplant.

[e] n = 5.

[f] For TTNtv present, n = 128.

Discussion

We demonstrate that truncating *TTN* mutations are frequently observed in patients with DCM who recover systolic function with standard medical therapy alone. Our results suggest that despite the key role played by *TTN* in cardiac function, individuals with these mutations can recover systolic function and are equally likely to experience recovery as those with other causes of DCM. While it was recently shown that recovery is possible in patients with DCM who have a truncating mutation in *TTN* with mechanical unloading therapy support, [2] [3] our findings that recovery is possible in those receiving medical therapy alone is consistent with another recently published study. [4] However, not all patients with *TTN* mutations receiving medical therapy recovered. While the specific mutations that cause DCM and their penetrance are known to play a role in age at onset and prognosis, [5] [6] to our knowledge, it remains unknown whether recovery from DCM also depends on the specific *TTN* mutation or penetrance. Because the recovery of left ventricular function in response to pharmacological therapy is variable, future studies should assess whether *TTN* mutations could affect the decision to continue medical therapy in patients with DCM who demonstrate sustained recovery.

Conclusions

Similar to other recent work, [4] our results suggest that further understanding of the variables that affect recovery from DCM, including the effect of genetics and their possible interactions with medical therapy, may be important in identifying each patient's long-term management.

Take Home Messages

- HFrecEF is suggested to be a distinct HF phenotype
- HFrecEF is not recovered HF, just having better EF
  - Prognosis, Biomarkers, GLPSS, functional capacity
- It is important to continue disease-modifying agents
- Clinical Guideline for HFrecEF to better tailor therapy is warranted
- Also genetics may play a role in the future treatment
