Heart disease

Prenatal diagnosis of structural heart disease: does it make a difference to survival?

I D Sullivan

Is there a survival advantage conferred by the prenatal diagnosis of congenital heart disease?

There are two potential advantages of mid trimester diagnosis of fetal heart disease. Perinatal management in an environment where the appropriate expertise is available and prepared might result in improved outcomes after intervention in the newborn period in situations where this is required. Alternatively, prenatal diagnosis of congenital heart disease allows consideration of termination of pregnancy. Termination of pregnancy for fetal anomaly is an emotive subject and has a wide range of acceptability in different societal contexts. Nearly 20% of all pregnancies in the UK were terminated for social indications in 1994 whereas the proportion in which the indication for termination was detection of fetal cardiac abnormality was about 0.02%.[1]

SURVIVAL ADVANTAGE?

If there is a survival advantage conferred by the prenatal diagnosis of congenital postnatal survival for live born infants with pulmonary atresia and intact ventricular septum was similar regardless of the timing of diagnosis in a large population based study.[4] The hypothesis that costs and duration of initial hospitalisation and survival to discharge home would be improved by prenatal diagnosis was examined in a cohort analysis of neonates with structural heart disease in the absence of other life threatening conditions.[5] There was no difference in survival among those requiring palliative surgery because of a functionally single ventricle. Moreover, the costs and duration of hospitalisation were greater in the group diagnosed prenatally, regardless of whether or not surgery was performed postnatally. The results were similar when the analysis was limited to infants whose survival was dependent on continued patency of the arterial duct.

to newborn infants in whom the same cardiac diagnosis was known prenatally. These factors may also explain why other studies of surgical patients have failed to demonstrate improved postoperative survival after prenatal diagnosis of hypoplastic left heart.[9–11] A recent report indicating improved hospital survival after initial staged palliative surgery for hypoplastic left heart following prenatal diagnosis[12] is more encouraging, but may not be directly comparable with previous data[6 8] as infants with birth weight less than 2 kg or serious extracardiac abnormality were excluded. In a report from a single surgical institution it is also difficult to exclude a selection bias in referral of prenatally diagnosed cases of hypoplastic left heart perceived to be good risk surgical candidates. Population based data may be better able to address this question.[1]

None of the studies cited above was designed to detect mortality resulting from neonatal death with congenital heart disease not diagnosed during life. Detection of this occult cardiac mortality allowed demonstration of improved survival after prenatal diagnosis of transposition of the great arteries in Paris.[13] By analogy, four critically ill newborn infants with respiratory failure and undiagnosed transposition of the great arteries have been referred to Great Ormond Street Hospital for ECMO (extracorporeal membrane oxygenation) support since 1994. However, the impact of prenatal diagnosis on improved postnatal survival will not be great in population terms while as little as 3% of all

Prenatal Diagnosis by Echocardiogram and Outcome of Absent Pulmonary Valve Syndrome

Reza S. Razavi, MRCP, Gurleen K. Sharland, MD, and John M. Simpson, MD

We reported echocardiographic findings and outcomes of fetuses with absent pulmonary valve syndrome diagnosed during fetal life. Cases were identified from a prospectively acquired computerized database of 18,308 pregnancies referred to a fetal cardiology center between January 1988 and July 2000. Twenty fetuses were identified with a median gestation of 23 weeks (range 18 to 36) at presentation. In 18 cases (90%), there was an associated ventricular septal defect. Eighteen cases (90%) had branch pulmonary artery diameters above the normal range. In four cases (20%), an arterial duct was present. A chromosome 22q11 deletion was identified in 2 of 9 cases (22%) in which this deletion was sought. There were 6 terminations of pregnancy (30%), 3 intrauterine deaths (15%), 5 neonatal deaths (25%), 3 infant deaths (15%), and 3 patients who did not die (15%). Ten of the 11 "liveborn" infants required early ventilation. The outcome of absent pulmonary valve symdrome diagnosed prenatally appears poor. The high morbidity and mortality is due to both cardiac disease and associated bronchomalacia. ©2003 by Excerpta Medica, Inc.

Tetralogy of Fallot with Absent Pulmonary Valve: Echocardiographic Morphometric Features of the Right-Sided Structures and their Relationship to Presentation and Outcome

Mary T. Donofrio, MD, Marshall L. Jacobs, MD, and Jack Rychik, MD, *Richmond, Virginia*

Respiratory symptoms in tetralogy of Fallot with absent pulmonary valve are believed to be due to bronchial compression secondary to dilated pulmonary arteries; however, not all patients are born compromised. Echocardiographic morphometry of the right-sided structures was investigated to determine the possible relationship between anatomy and clinical presentation. Twenty-five patients were identified, and 15 had preoperative echocardiograms. Patients were divided into two groups: those with respiratory distress (group I, $n = 9$) and those without (group II, $n = 6$). No difference was noted in branch pulmonary artery diameters between groups; however, the pulmonary valve/aortic valve ratio, reflecting the dimension of the narrowest pathway from the right ventricle, was larger in group I (0.74 ± 0.15 versus 0.60 ± 0.07, $p < 0.05$). Pulmonary valve diameter correlated with main and right pulmonary artery diameters. We conclude that patients with tetralogy of Fallot with absent pulmonary valve and respiratory compromise have a greater pulmonary valve/aortic valve ratio but do not have greater dilatation of proximal branch pulmonary arteries. This suggests that the pathophysiology is not due solely to compression of the bronchi but is also related to the blood flow dynamics in the pulmonary vessels. (J Am Soc Echocardiogr 1997;10:556-61.)

Tetralogy of Fallot with absent pulmonary valve (TOF/APV) is a rare form of congenital heart disease with a wide spectrum of clinical presentations. Despite the continued improvement in surgical techniques and

cause for these findings in the face of a primary cardiovascular deformity are unsettled and speculative. Pulmonary artery dilatation has been hypothesized to be related to an intrinsic defect in the pulmonary vascula-

Value of Clinical and Echocardiographic Features in Predicting Outcome in the Fetus, Infant, and Child With Tetralogy of Fallot With Absent Pulmonary Valve Complex

Anita J. Moon-Grady, MD, Theresa A. Tacy, MD, Michael M. Brook, MD, Frank L. Hanley, MD, and Norman H. Silverman, MD, DSc (Med)

We describe clinical and echocardiographic features of tetralogy of Fallot with absent pulmonary valve complex (TOF/APVC) and hypothesized that outcome might be related to pulmonary artery enlargement or severity of illness. We examined the clinical records of all 23 patients evaluated at our institution before death or surgical correction of TOF/APVC between 1990 and 2000. Echocardiograms for 16 patients (including 5 fetuses) were also reviewed, and measurements of the semilunar valves and pulmonary arteries were obtained and compared with patient's aortic annulus size and with established normal subjects. Actuarial survival was 15 of 23 patients (68%) at 4 years. Four fetuses were hydropic and none survived; 7 patients were ventilator dependent at operation and only 3 survived. No difference was noted in pulmonary artery diameters in survivors versus nonsurvivors. Pulmonary valve annulus size was larger in nonsurvivors (103 ± 25% vs 71 ± 24% of normal, $p = 0.03$); however, when fetal examinations were excluded, this difference did not persist. Thus, only hydrops and ventilator dependence at diagnosis predicted mortality. There was no correlation between postnatal measurements of pulmonary arteries and outcome. Larger pulmonary annulus size in hydropic fetuses and poor survival among patients diagnosed in utero suggests that the pathophysiology in TOF/APVC is not due entirely to the aneurysmal dilation of the pulmonary arteries but may be related to right-sided cardiac dysfunction. ©2002 by Excerpta Medica, Inc.

Anatomic Variability and Outcome in Prenatally Diagnosed Absent Pulmonary Valve Syndrome

Anita Szwast, MD, Zhiyun Tian, MD, Margaret McCann, RDCS, Debbra Soffer, RDCS, Jill Combs, RN, MSN, Denise Donaghue, RN, MSN, and Jack Rychik, MD

The Fetal Heart Program at the Cardiac Center at the Children's Hospital of Philadelphia; and The University of Pennsylvania School of Medicine, Department of Pediatrics, Division of Cardiology, Philadelphia, Pennsylvania

Background. We sought to describe current outcomes and risk factors for mortality for fetuses diagnosed with absent pulmonary valve syndrome (APV). Fetuses with APV were divided into two cohorts, those with underlying tetralogy of Fallot (TOF/APV) and those without underlying TOF and either an intact ventricular septum or small ventricular septal defect (APV/IVS).

Methods. The fetal echocardiographic database was reviewed from January 1, 2001, until June 1, 2010, and all subjects with a diagnosis of APV were included. Multiple clinical and fetal echocardiographic measurements were recorded. Statistical analysis was performed by χ^2 analysis and t tests. Survival analysis was performed by Kaplan-Meier analysis. Significant relationships between variables were explored by regression analysis. Significance was set at $p = 0.05$.

Results. The cohort consisted of 15 fetuses with TOF/APV and 6 fetuses with APV/IVS. There were no fetal demises in either cohort. Survival to birth was 71% in the TOF/APV cohort and 83% in the APV/IVS cohort ($p = 0.62$). Of subjects born alive, survival was 80% for both cohorts ($p = 0.95$). However, in the APV/IVS cohort, transplantation-free survival was only 20%. Underlying single-ventricle physiology strongly predicted those who underwent heart transplantation ($p = 0.003$, $R^2 = 0.50$). For the entire APV cohort, left ventricular dysfunction ($p = 0.005$, $R^2 = 0.41$) and a higher pulmonary artery valve–to–aortic valve ratio ($p = 0.02$, $R^2 = 0.34$) predicted mortality.

Conclusions. Postnatal outcomes continue to improve for fetuses with APV syndrome. Left ventricular dysfunction and higher pulmonary artery valve–to–aortic valve ratio accurately predict postnatal mortality for fetuses with APV.

Prenatal Role of the Ductus Arteriosus in Absent Pulmonary Valve Syndrome

Scott B. Yeager, M.D.,* Mary E. Van Der Velde, M.D.,† Brenda L. Waters, M.D.,‡ and Stephen P. Sanders, M.D.§

*Department of Pediatrics, University of Vermont School of Medicine, Burlington, Vermont, †Department of Cardiology, Harvard Medical School and the Children's Hospital, Boston, Massachusetts, ‡Department of Pathology, University of Vermont School of Medicine, Burlington, Vermont, and §Department of Cardiology, Harvard Medical School and the Children's Hospital, Boston, Massachusetts

Absent pulmonary valve with ventricular septal defect is associated with ductal agenesis and markedly dilated main and branch pulmonary arteries. The less common variant with intact ventricular septum generally exhibits a patent ductus and smaller branch pulmonary arteries, and may be associated with tricuspid atresia. We identified 7 patients with the prenatal diagnosis of absent pulmonary valve, 5 with ventricular septal defect (Group 1) and 2 with an intact ventricular septum (Group 2). Imaging, color Doppler, and pulsed-Doppler recordings were analyzed. The branch and main pulmonary arteries were measured and expressed as a ratio with the descending aorta. Pulmonary regurgitation time (PRT) and diastolic acceleration time (DAT) were derived, and DAT/PRT was calculated to characterize diastolic pulmonary flow. Group 1 patients all had a large ventricular septal defect, normal biventricular size and function, and dilated main and branch pulmonary arteries. Group 2 patients had dilated main but smaller branch pulmonary arteries, moderate right ventricular dilation with severe dysfunction, and limited or absent tricuspid inflow. Group 1 demonstrated shorter acceleration time and earlier peak velocity, resulting in a smaller DAT/RT ratio. We speculate that free communication between the fetal aorta and the ventricles may limit atrial inflow and elevate diastolic pressure, affecting cardiac output, ventricular function, and atrioventricular valve development. With an intact ventricular septum, these physiologic and anatomic repercussions are limited to the right ventricle, but with a ventricular septal defect, both ventricles would experience similar consequences and cardiac performance could be critically impaired. KEYWORDS: absent pulmonary valve syndrome; congenital heart defect; fetus; prenatal diagnosis; tetralogy of Fallot

ABSTRACT

Objective *To assess the spectrum of associated anomalies, intrauterine course and outcome in fetuses with absent pulmonary valve syndrome (APVS).*

Methods *All cases with a prenatal diagnosis of APVS at two centers over a period of 13 years were analyzed retrospectively. APVS was diagnosed in the presence of rudimentary or dysplastic pulmonary valve leaflets with to-and-fro blood flow in the pulmonary trunk on color and pulsed-wave Doppler ultrasound. Data on demographic characteristics, presence of associated conditions, Doppler studies and pregnancy outcome were reviewed.*

eight had hydrops and/or increased nuchal translucency, six were associated with trisomy 13 or 18 and none survived.

Conclusion *APVS diagnosed in the first trimester is significantly associated with TOF, patency of the DA, abnormal Doppler parameters, lethal trisomies and intrauterine mortality. Cases of APVS with isolated TOF and agenesis of the DA have a better outcome than those with additional anomalies, with > 80% survival.*

INTRODUCTION

Take home messages

- Overall outcomes of prenatally diagnosed APVS are bad, but fetal demise is rare.
- Prenatal risk factors for bad outcome

  A. Fetal hydrops

  B. Large PVA size (high PVA/AVA ratio)

  C. Ventricular dysfunction

  D. APVS with FSV, APVS with IVS

  E. High DAT/PRT of dutal flow reversal

  F. Genetic: CHARGE, Catch-22. fatal trisomies (13, 18)
